gasket—A device used to retain fluids under pressure or seal out foreign matter. Also a static seal to reduce electromagnetic interference or susceptibility.

gasket-sealed relay—A relay in an enclosure sealed with a gasket.

gas laser—Also called gas-discharge laser. A laser in which the active medium is a discharge in gas, vapor, or mixture within a glass or quartz tube that has a Brewster window at each end. This gas can be excited by a high-frequency oscillator or by a direct current between electrodes inside the tube to pump the medium so as to obtain a population inversion.

gas magnification—The increase in current through a phototube due to ionization of the gas within the tube.

gas maser—A maser in which the microwave electromagnetic radiation interacts with the molecules of a gas such as ammonia. Use is limited chiefly to highly stable oscillator applications, as in atomic clocks.

gas noise—Electrical noise produced by erratic motion of gas molecules in gas or partially evacuated vacuum tubes.

gas-phase laser—A continuous-wave device for general experimental work with coherent light. It employs

a resonator made up of a fused-silica plasma tube 60 cm long having internal, multilayer, dielectric-coated confocal reflectors of optical-grade fused silica.

gas photocell—A photoemissive cell having an inert gas added to its envelope. Subsequent ionization of the gas increases the responsivity of the photocell.

gas phototube—A phototube into which a quantity of gas has been introduced, usually to increase its sensitivity.

gas ratio—The ratio of the ion current in a tube to the electron current that produces it.

gassiness—The presence of unwanted gas in a vacuum tube, usually in relatively small amounts. It is caused by leakage from outside the tube or by evolution from its inside walls or elements.

gassing—1. Evolution of a gas from one or more electrodes during electrolysis. 2. The production of gas in a storage battery when the charging current is continued after the battery has been completely charged.

gassy—Having operating characteristics that are impaired as a result of an excessive amount of gas inside its envelope, as a vacuum tube.

gassy tube—See soft tube.

gas-tight connection—A contact or joint that prevents contaminant gases from reaching the contact area.

gaston—A modulator that produces a random-noise modulation signal from a gas tube. It may be attached to any standard aircraft communications transmitter to provide a counterjammng modulation.

gas tube—1. A partially evacuated electron tube containing a small amount of gas. Ionization of the gas molecules is responsible for the current. 2. An electron tube whose current is affected by the pressure on the gas or vapor contained in the tube.

gas-tube relaxation oscillator—A relaxation oscillator in which the abrupt discharge is provided by the breakdown of the gas in the tube.

gas X-ray tube—An X-ray tube in which electron emission from the cathode is produced by bombarding it with positive ions.

gate—1. A circuit having two or more inputs and one output, the output depending upon the combination of logic signals at the inputs. There are four gates, called

AND, OR, NAND, and NOR. The definitions assume positive logic is used. In computer work, a gate is often called an AND circuit. 2. A signal used to trigger the passage of other signals through a circuit. 3. One of the electrodes of a field-effect transistor; it is analogous to the base of a transistor or the grid of a vacuum tube. Symbol: G. 4. An output element of a cryotron. 5. A circuit in which one signal (usually a square wave) switches another signal on or off. 6. To control the passage of a pulse or signal. 7. Voltage-actuated control terminal of an MOS transistor. 8. A circuit that admits and amplifies or passes a signal only when a gating (triggering) pulse is present. 9. A digital logic element usually with one output and several inputs, where the output is a function of a combination of the inputs. 10. A single logic function, such as NAND, NOR, AND, OR, XOR, or NOT.

gate array—1. A geometric pattern of basic gates contained in one chip. It is possible to interconnect the gates during manufacture to form a complex function that may be used as a standard production. 2. A cellular arrangement of logic elements with a custom interconnection. Arrays offer complexities of several hundred to more than 2000 gates, performance that equals or betters that of standard TTL or ECL, and as little as 12-week turnaround from design to prototype. 3. Also called a semicustom large-scale integrated or very large-scale integrated circuit (VLSI). A matrix of unconnected transistors and resistors that become a dedicated array only after they are interconnected by one or more masking and interconnection steps. The term *gate array* is a holdover from the days when functional logical cells, equivalent to small- and medium-scale integrated circuits, were made by first forming equivalent gates. 4. Cells of transistors stacked in columns and separated by conductive channels. The cells are selectively connected to the channels in the final stages of manufacturing to provide logic functions. Like PLAs, gate arrays are less space efficient and more expensive than dedicated circuits. 5. A semicustom IC consisting of a regular arrangement of gates that are interconnected through one or more layers of metal to provide custom functions. Generally, gate arrays are preprocessed up to the first interconnect level so they can be quickly processed with final metal to meet a customer's specified logic function.

gate circuit—A circuit that passes a signal only when a gating pulse is present.

gate-controlled switch—Also called gate turn-off switch. A three-junction, three-terminal, solid-state device constructed very much like a silicon-controlled rectifier except that it has a turn-off ability, which is controlled by a negative current pulse applied to the gate.

gate-controlled turn-off time—1. The time interval during which a thyristor is switching from the on state to the off state as a result of the application of a gate trigger pulse. The interval is usually measured from the 10-percent point on the gate pulse to the instant at which the principal voltage has increased to 90 percent of the off-state voltage. 2. The time interval during which a thyristor is switching from the off state to the on state as a result of the application of a gate trigger pulse. The interval is usually measured from the 10-percent point on the gate pulse to the instant at which the principal voltage has dropped to 10 percent of its initial value. The turn-on time is the sum of the delay time and the rise time.

gate-controlled turn-on time—The time interval between the 10-percent rise of the gate pulse and the 90-percent rise of the principal current pulse during switching of a thyristor from the off state to the on state.

gate current—Instantaneous current flowing between the gate and cathode of a silicon-controlled rectifier.

gate current for firing—Gate current required to fire a silicon-controlled rectifier when the anode is at a fixed dc voltage with respect to the cathode and with the device at stated temperature conditions.

gated-beam detector—A single-stage FM detector using a gated-beam tube.

gated-beam tube—A five-element tube in which the electrons flow in a beam between the cathode and plate. A small increase in voltage on the limiter grid will cut off the plate current, and further increases will have a negligible effect on it.

gated buffer—A low-impedance inverting driver circuit that may be used as a line driver for pulse differentiation or in multivibrators.

gated flip-flop—A flip-flop that has a steering circuit that prevents both flip-flop outputs from becoming 0 at the same time. Alternating-current input pulses must be used to prevent the flip-flop from oscillating. This situation can arise if both input lines are made high simultaneously.

gated sweep—Sweep in which the duration as well as the starting time is controlled to exclude undesired echoes from the indicator screen.

gated transistor—A transistor in which a gate electrode covers the emitter and collector junctions. This allows the application of an electric field at the surface of the base region.

gate electrode—A control electrode to which trigger pulses are applied.

gate equivalent circuit—A basic unit for describing relative digital circuit complexity. The number of gate equivalent circuits is that number of individual logic gates that would have to be interconnected to perform the same function.

gate generator—A circuit or device used to produce one or more gate pulses.

gate impedance—The impedance of a gate winding in a magnetic amplifier.

gate multivibrator—A rectangular-wave generator designed to produce a single positive or negative gate voltage upon being triggered and then to become inactive until the arrival of the following trigger pulse.

gate nontrigger current—The highest gate current that will not cause a thyristor to switch from the off state to the on state.

gate nontrigger voltage—The maximum gate voltage that will not cause a thyristor to switch from the off state to the on state.

gate power dissipation—The power dissipated between the gate and cathode terminals of a silicon-controlled rectifier.

gate-producing multivibrator—A rectangular-wave generator that produces a single positive or negative gate voltage only when triggered by a pulse.

gate pulse—A pulse that enables a gate circuit to pass a signal. The gate pulse generally has a longer duration than the signal to ensure time coincidence.

gate region—Of a field-effect transistor, a region associated with the gate electrode in which the electric field due to the control voltage is effective.

gate resistance—The dc resistance between gate and source terminals of a field-effect transistor at specified gate voltage with drain short-circuited to the source.

gate signal—That signal generated by some form of delay circuit required in connection with beam switching, automatic following, the application of AGC to a selected echo, and many other purposes.

gate terminal—1. The terminal in a field-effect transistor electrically connected to the electrode associated with the region in which the electric field, due to the

control voltage, is effective. 2. A terminal to or from which only control current, usually called the gate current, flows.

gate-to-source leakage current—A current through gate and source terminals of a field-effect transistor at specified drain circuit conditions.

gate trigger current—In a controlled rectifier, the minimum gate current, for a given anode-to-cathode voltage, required to switch the rectifier from the off state to the on state.

gate trigger voltage—In a controlled rectifier, the gate voltage that produces the gate trigger current.

gate tube—A tube that does not operate unless two signal voltages, derived from two independent circuits, are applied simultaneously to two separate electrodes.

gate turn-off current—In a controlled rectifier, the minimum gate current, for a given collector current in the on state, required to cause the rectifier to switch off. Not all thyristors can be turned off by the gate.

gate turn-off switch—*See* gate-controlled switch.

gate turn-off voltage—The gate voltage required to produce the gate turn-off current in a thyristor. Not all thyristors can be turned off by the gate.

gate voltage—1. The voltage across the gate-winding terminals of a magnetic amplifier. 2. The instantaneous voltage between gate and cathode of a silicon-controlled rectifier with anode opening. 3. The voltage between a gate terminal and a specified main terminal.

gateway—1. A link, or bridge, from one type of communication network to another. 2. A machine or set of machines used to relay packets from one network to another network. *See also* router. 3. Equipment used to connect network architectures that use different protocols by providing protocol translation. 4. A link from one computer system to a different computer system. Some gateways are the Internet and Stocklink.

gateway station—An earth station that provides mobile units with access to the public telephone network.

gate winding—The reactor winding that produces the gating action in a magnetic amplifier.

gating—1. Selecting those portions of a wave that exist during certain intervals or that have certain magnitudes. 2. Applying a rectangular voltage to the grid or cathode of a cathode-ray tube, to sensitize it during the sweep time only. 3. Application of a specific waveform to perform electronic switching. *See also* blanking.

gating circuit—A circuit that operates as a selective switch and allows conduction only during selected time intervals or when the signal magnitude is within specified limits.

gating pulse—A pulse that modifies the operation of a gate circuit.

gauge—*See* gage.

gauge pressure—*See* gage pressure.

gauss—1. The centimeter-gram-second electromagnetic unit of magnetic induction. One gauss represents one line of flux (one maxwell) per square centimeter. Letter symbol: G.

Gaussian distribution—Also called normal distribution. A density function of a population that is bell-shaped and symmetrical and that is completely defined by two independent parameters: the mean and the standard deviation.

Gaussian elimination—A method for solving systems of linear equations based on manipulation of the matrix representing those equations.

Gaussian function—A mathematical function used in designing a filter to pass a step function with zero overshoot and minimum rise time (similar to a Bessel-function filter).

Gaussian noise—1. Unwanted electrical disturbances or perturbations described by a probability density function that follows a normal law of statistics. This normal distribution is the well-known symmetrical bell-shaped density function of a population that is completely defined by two independent parameters, viz, the mean and the standard deviation. The Gaussian (normal) amplitude distribution is of fundamental significance in statistical theory, describing numerous natural phenomena. The central-limit theorem of statistics states, in essence, that the sum of a number of independent random variables approaches the Gaussian distribution as the number of said variables increases, regardless of the distribution of the individual variables. A significant facet of Gaussian random noise is that it exceeds its positive root-mean-square amplitude and attains twice that value for 16 and 20 percent of the time, respectively. 2. A random-noise signal whose frequency components have a Gaussian distribution centered on a specified frequency. 3. Noise whose amplitude is characterized by the Gaussian distribution, e.g., white noise, ambient noise, and hiss.

Gaussian random vibration—*See* random vibration.

Gaussian waveform—In pulse-compression systems, a waveform that produces very low transmitted side lobes.

gaussmeter—An instrument that provides direct readings of magnetic field density (flux density) by virtue of the interaction with an internal magnetic field.

Gauss's theorem—The summation of the normal component of the electric displacement over any closed surface is equal to the electric charge within the surface.

GB—Abbreviation for gigabyte, one billion bytes.

GCA—Abbreviation for ground-controlled approach.

GCI—Abbreviation for ground-controlled interception.

GCS—Abbreviation for gate-controlled switch.

GCT or Gct—Abbreviation for Greenwich civil time.

G-display—Also called G-scan or G-scope. In radar, a rectangular display in which a target appears as a laterally centralized blip on which wings appear to grow as the target approaches. Horizontal and vertical aiming errors are indicated by horizontal and vertical displacement of the blip.

gear—An element shaped like a toothed wheel that engages one or more similar wheels. The energy transmitted can be stepped up or down by making the driven gears of different sizes.

geared synchro system—A system in which the transmitting and receiving synchros turn at a higher speed than the input and output shafts. Geared systems are generally used when a high degree of accuracy is required.

garmotor—A train of gears and a motor used for reducing or increasing the speed of the driven object.

Geiger counter—Also called Geiger-Mueller or G-M counter. 1. A radiation detector that uses a Geiger-Mueller counter tube, an amplifier, and an indicating device. The tube consists of a thin-walled gas-filled metal cylinder with a projecting electrode. Nuclear particles enter a window in the metal cylinder and temporarily ionize the gas, causing a brief pulse discharge. These pulses, which appear at the projecting electrode, are amplified and indicated visibly or audibly. 2. Gas-chamber-type radiation counter in which the chamber operates in avalanche region for high amplification and sensitivity.

Geiger-Mueller counter—*See* Geiger counter.

Geiger-Mueller counter tube—A radiation-counter tube designed to operate in the Geiger-Mueller region.

Geiger-Mueller region — Also called Geiger region. The voltage interval in which the pulse size is independent of the number of primary ions produced in the initial ionizing event.

Geiger-Mueller threshold — Also called Geiger threshold. The lowest voltage at which all pulses produced in the tube by any ionizing event are of the same size regardless of the size of the primary ionizing event. This threshold is that start of the Geiger region in which the counting rate does not substantially change with applied voltage.

Geiger region — See Geiger-Mueller region.

Geiger threshold — See Geiger-Mueller threshold.

Geissler tube — A gas-filled dual-electrode discharge tube that glows when electric current passes through the gas.

gel — A material composed of a solid held in a liquid.

genemotor — A type of dynamotor having two armature windings. One winding serves as the driving motor and operates from the vehicle battery. The other winding functions as a high-voltage dc generator for operation of mobile equipment.

general address — Group of characters included in the heading of a message to cause routing of the message to all addresses included in the general address category.

general background lighting — Overall lighting level in a room or area, exclusive of local lighting.

general class license — A license issued by the FCC to amateur radio operators who are able to send and receive code at the rate of 13 words per minute and who are familiar with general radio theory and practice. Holder enjoys all authorized amateur privileges except those reserved for higher license classes.

generalized network — A set of elements, commonly called nodes, that are interconnected in some way. In some cases it is sufficient to assign some meaning to the nodes and interconnections for the network to have some useful purpose. For example, a PERT network is simply a planning model of a complex set of tasks to be performed. Each node represents the completion of a task. The interconnecting lines represent precursor and successor relationships among tasks. Such models are commonly used to determine the critical path—the most complex sequence of events that will complete the task.

general light — The total light or light level in a room or area, including all sources.

general-purpose computer — A computer designed to solve a wide variety of problems, the exact nature of which may have been unknown before the computer was designed.

general-purpose digital computer — A digital computer designed to solve a large variety of problems; that is, a computer that can be adapted to a large class of applications (as opposed to a computer designed specifically to control a manufacturing process). A typical general-purpose digital computer consists of four subsystems: (1) input/output, which permits communication with the outside world; (2) memory, which stores data

and instructions; (3) central processing unit (CPU), or arithmetic unit, which performs the arithmetic and data processing operations; and (4) control, which ties all of the subsystems together so that they operate in a fully automated way.

general-purpose interface bus — See GPIB.

general-purpose motor — A motor of 200 hp or less and 450 rpm or more, rated for continuous operation, having standard ratings, and suitable for use without restriction to a particular application.

general-purpose relay — A term that covers a wide variety of electromechanical relays that typically are of the common coil-and-armature type, the most common styles having the ability to switch either ac or dc with dc ratings from 2 to 10 amperes. These relays are usually employed in switching power and can be found in business machines, process controls, fractional-horsepower motor controls, and many other applications. They may be plug-in, bracket, stud, or screw mounted. Plug-in choices are square, octal, miniature, and multiple-pin. A relay that is adaptable to a variety of applications.

general rate — The amount of time taken by the creation of electron-hole pairs in a semiconductor.

general register — One of a specified number of internal addressable registers in a CPU that can be used for temporary storage, as an accumulator, an index register, a stack pointer, or for any other general-purpose function.

general routine — A computer routine designed to solve a general class of problems, but when appropriate parametric values are supplied, it specializes in a specific problem.

generated noise — In potentiometric transducers, the noise that is attributable to causes such as the generation of emf when dissimilar metals are rubbed against each other, or the emf resulting from the thermocouple effects at points where dissimilar metals are joined.

generating electric field meter — Also called a gradient meter. A device for measuring the potential gradient at the surface of a conductor. A flat conductor is alternately exposed and then shielded from the electric field to be measured. The resultant current in the conductor is then rectified and used as the measure.

generating magnetometer — Also called earth inductor. A magnetometer that measures a magnetic field by the amount of emf generated in a coil rotated in the field.

generating station — An installation that produces electric energy from chemical, mechanical, hydraulic, or some other form of energy.

generating voltmeter — Also called a rotary voltmeter. A device that measures voltage. A capacitor is connected across the voltage, and its capacitance is varied cyclically. The resultant current in the capacitor is then rectified and used as a measure.

generation — The number of dubbing steps between a master recording and a given copy of the master. Thus, a second-generation dub is a copy of a copy of the original master.

generation data group — A collection of successive data sets that are historically related.

generation rate — The time rate of creation of electron-hole pairs in a semiconductor.

generator — Symbolized G. Also called dynamo. 1. A machine that converts the mechanical energy of a spinning rotor into electrical energy. 2. An electronic device that converts dc voltage to alternating current of the desired frequency and waveshape. 3. Any device that generates electricity. 4. In computer operation, a routine for producing specific routines from specific input parameters and skeletal coding. 5. A machine that

General-purpose digital computer.

converts mechanical energy into electric energy. In its commonest form, a large number of conductors are mounted on an armature that is rotated in a magnetic field produced by field coils. 6. A vacuum-tube oscillator or any other nonrotating device that generates an alternating voltage at a desired frequency when energized with dc power or low-frequency ac power. Such generators are used to produce large amounts of rf power, such as for high-frequency heating and ultrasonic cleaning. 7. A circuit that generates a desired repetitive or nonrepetitive waveform, such as a pulse generator.

generator efficiency—1. In a generator, the ratio between the power required to drive the generator and the output power obtained from it. 2. In a thermoelectric couple, the ratio of the electrical power output to the thermal power input. It is an idealized efficiency assuming perfect thermal insulation of the thermoelectric arms.

generator field control—Regulation of the output voltage of a generator by control of the voltage that excites the field winding of the generator.

generator lock—*See* genlock.

generator voltage regulator—A regulator that maintains or varies the voltage of a synchronous generator, capacitor motor, or direct-current generator at or within a predetermined value.

generic package—A collection of software items from which more than one installation-dependent specific package may be generated by a software manufacturing process. Generic packages may be in source-code form (generic source package) or in object-code form (generic object package).

genlock—Abbreviation for generator lock. Also abbreviated GENLOCK. 1. When two composite video signals are mixed, or one is fed as input to another, their vertical, horizontal and subcarrier signals must be synchronized exactly or with a fixed offset. Genlock is achieved by means of locking the originating signal with the second with a digital or analog phase-locked loop circuit. 2. A process of sync generator locking, that makes it possible for two sync generators to run at the same frequency and phase. Used in video processing.

geodesic—The shortest line between two points on a given surface.

geometric distortion—In television, any geometric dissimilarity between the original scene and the reproduced image.

geometric mean—The square root of the product of two quantities.

geometric symmetry—Filter response in which there is mirror-image symmetry about the center frequency when frequency is plotted on a logarithmic scale. (This is the natural response of many electrical circuits.) *See also* arithmetic symmetry.

geometry—The shape or configuration of a die or IC.

geophysical cable—Cable used in exploring for underground oil deposits.

george box—An amplitude-sensitive device employed in an intermediate-frequency amplifier. It rejects jamming signals of insufficient amplitude to operate its circuits; however, jamming signals having sufficient amplitude are not affected.

geostationary—Refers to a geosynchronous satellite angle with zero inclination so that the satellite appears to hover over one spot on the earth's equator. A satellite in the Clarke belt is geostationary.

geostationary orbit—Also called Clarke orbit, in honor of Arthur C. Clarke, who first described it. This circular orbit above the equator is precisely the altitude (35,863 km or 22,238 miles) at which any size satellite will revolve around the earth once every 24 hours.

From the ground below it thus appears parked in space overhead, and, from above, one-third of the earth's surface can always be seen. Television satellites are separated by 4° intervals on this orbit to avoid mutual interference.

geosynchronous—Within the Clarke circular orbit above the equator. For a planet the size and mass of the earth, this point is 22,238 miles above the surface.

geosynchronous satellite—A satellite positioned at the proper distance from the earth and moving at the proper relational speed to appear stationary to an observer on earth.

germanium—Symbol Ge. A brittle, grayish-white metallic element having semiconductor properties. Widely used in transistors and crystal diodes. Its atomic number is 32.

germanium detector—A type of photoconductive detector in which germanium, usually doped with boron, gallium, and indium, serves as a semiconductor and can detect frequencies up to and beyond 100 micrometers.

germanium diode—A semiconductor diode in which a germanium crystal pellet is used as the rectifying element.

germanium transistor—A transistor in which germanium is the semiconducting material.

German silver—Usually called nickel silver. A silvery alloy of copper, zinc, and nickel.

getter—An alkali metal introduced into a vacuum tube during manufacture. It is fired after the tube has been evacuated, to react chemically with and eliminate any remaining gases. The getter then remains inactive inside the tube. The silvery deposit sometimes seen on the inside of the glass envelope is due to getter firing.

gettering—A semiconductor manufacturing process that aims to remove defects from the neighborhood of the devices, either removing them completely from the silicon wafer or transporting them into regions where they will have no effect on device performance. Defects can be introduced at almost any time during processing, and the defects can take on many forms. Consequently, a large number of different types of gettering processes are presently used. Several different gettering processes may be used during the fabrication of one particular device.

G force—*See* g.

g-g—Abbreviation for ground-to-ground. Communication between two points on the ground.

ghost—1. A spurious video image resulting from an echo. 2. An undesired duplicate image in a television picture, fainter and to one side of the normal picture, due to multipath transmission. *See* ghost image.

ghost image—Also called ghost. An undesired duplicate image offset somewhat from the desired image as viewed on a television screen. It is due to a reflected signal traveling over a longer path and, hence, arriving later than the desired signal. It may be eliminated by the use of a directional antenna array that receives signals over only one path.

ghosting—The appearance of multiple TV images, which is usually caused by reception of a signal via two different paths.

ghost mode—A waveguide mode in which there is a trapped field associated with an imperfection in the waveguide wall. A ghost mode can cause difficulty in a waveguide operated near the cutoff frequency of a propagation mode.

ghost pulse—*See* ghost signal.

ghost signal—Also called ghost pulse. An unwanted signal on the screen of a radar indicator. Echoes that experience multiple reflections before reaching the receiver are an example. The term also is applied to a reflected television signal. *See* ghost image.

*Ghost signal.*

giant grid — An extensive regional or national system of backbones and networks.

giant ties — See interconnection, 1.

Gibson girl — A portable, hand-operated transmitter used by pilots forced down at sea.

GIF — Abbreviation for Graphics Interchange Format. A standard color image format commonly encountered on the Internet. Other common formats are TIFF, PICT, and JPEG.

giga- — A prefix meaning one billion, or 10^9 .

gigacycle — One kilomegacycle, or one billion cycles. An obsolete term. The currently preferred term is gigahertz.

gigahertz (GHz) — One billion (10^9) cycles per second. Used to replace the more cumbersome and obsolete term *kilomegacycle*.

gigawatt — One thousand megawatts (10^9 watts). Letter symbol: GW.

GIGO or gigo — 1. An acronym formed from the phrase “garbage in, garbage out.” It is used to describe a computer whose operation is suspect. 2. A term used to describe data moving into and out of a computer system. If the input is bad (garbage in), then the output will also be bad (garbage out).

gigohm — One thousand megohms (10^9 ohms).

gilbert — A cgs unit of the magnetomotive force required to produce one maxwell of magnetic flux in a magnetic circuit of unit reluctance; 1 gilbert = $10/4\pi$ ampere-turn. Letter symbol: Gb.

gilbert per centimeter — The practical cgs unit of magnetic intensity. Gilberts per centimeter are the same as oersteds.

Gill-Morrell oscillator — A retarding-field oscillator in which the oscillation frequency depends not only on the electron transit time within the tube, but also on the associated circuit parameters.

gill selector — A slow-acting telegraph sender and calling key for selective signaling.

gimbal — A mechanical frame having two perpendicularly intersecting axes of rotation.

gimmick — 1. A capacitor with a value of a few picofarads, improvised by twisting together two insulated wires. 2. Length of twisted two-conductor cable used as a variable-capacity load, in which the capacity is varied by untwisting and separating the individual conductors.

gimp — A slang name given to the extremely flexible wire that was used in telephone cords and similar equipment. This wire cannot be directly soldered to, as it is a metallic cloth-type material.

Giorgi system — See mksa electromagnetic system of units.

glass — In fiber optics, an amorphous transparent or translucent brittle material usually made by fusion of silica, soda ash, lime, and salt cake or similar materials. Used as a fiber-optic cable, glass offers resistance to high

temperatures. It is not subject to corrosion, and eliminates fire hazards and problems caused by short circuits.

glass-ambient technology — The technique by which glass is applied directly to the surface of a semiconductor material. Typically, glass is placed on the surface of a microelectronic device by means of pyrolytic deposition, vapor deposition, or the firing of a glass powder to the surface.

glass binder — The glass powder added to a resistor or conductor ink to bind the metallic particles together after firing.

glassbreak vibration detector — A vibration-detection system that employs a contact microphone attached to a glass window to detect cutting or breakage of the glass.

glass electrode — In electronic pH measurement, an electrode used for determining the potential of a solution with respect to a reference electrode. The calomel type is the most common.

glassivation — Also called passivation. 1. A method of transistor passivation by a pyrolytic glass-deposition technique, whereby silicon semiconductor devices, complete with metal contact systems, are fully encapsulated in glass. 2. The deposition of glass on a chip to give protection to underlying device junctions. 3. A process in which a dielectric material is diffused over the entire wafer to provide mechanical and environmental protection for the circuits. 4. A method of semiconductor passivation by coating the element with a pyrolytic glass deposition.

glass-plate capacitor — A high-voltage capacitor in which the metal plates are separated by sheets of glass for dielectric. The complete assembly is generally immersed in oil.

glass-to-metal seal — An airtight seal between glass and metal parts of an electron tube, made by fusing together a special glass and special metal alloy having nearly the same temperature coefficients of expansion.

glass tube — A vacuum or gaseous tube that has a glass envelope.

glazed substrate — Ceramic substrate with a glass coating to effect a smooth and nonporous surface.

glide path — The approach path used by an aircraft making an instrument landing.

glide-path localizer — In an aircraft instrument-landing system, the part that indicates the altitude of the plane and creates a glide path for a blind landing.

glide-path transmitter — A transmitter that produces signals for vertical guidance of aircraft along an inclined surface that extends upward from the desired point of ground contact.

glide slope — A radio beam used by pilots to determine the altitude of the aircraft during a landing.

glide-slope facility — A radio transmitting facility that provides the glide-slope signals.

glidetone — A device used in electronic music that produces a continuous shift in the frequency of an audio signal.

G-line — 1. A round wire coated with a dielectric and used to transmit microwave energy. 2. A signal insulated wire that can be strung in the open and used as a surface-wave radio-frequency transmission line. A G-line acts like a coaxial cable without the outer tubular conductor.

glint — Also called glitter. 1. A distorted radar-signal echo that varies in amplitude from pulse to pulse because the beam is being reflected from a rapidly moving object such as an airplane propeller. 2. An electronic-countermeasures technique in which the scintillating effect of shuttered or rotating reflectors is used to degrade the tracking or seeking functions of an enemy weapons system.

glissando—A tone that changes smoothly from one pitch to another.

glitch—1. A form of low-frequency interference appearing as a narrow horizontal bar moving vertically through the television picture. This is also observed on an oscilloscope at the field or frame rate as an extraneous voltage pip moving along the signal at approximately the reference-black level. 2. An unwanted transient condition. 3. An undesired pulse or burst of noise that causes crashes and failures in computers. A small pulse of noise is called a snivitz. 4. A temporary or random error, or a problem or malfunction in hardware, such as a malfunction that can be caused by a power surge. 5. A spike caused by the skew (difference in turn-on/turn-off time) of switches or logic. Glitches are a troublesome source of error in high-speed D/A converters and are most prevalent at the midscale switching location, when all digital input bits are switching. Glitch energy is specified in picovolt-seconds, which describes the area under the voltage-time curve at its worst-case occurrence.

glitter—See glint.

global beam—1. An INTELSAT antenna downlink pattern covering a third of the earth's surface. These patterns are bore-sighted at the middle of an ocean to provide services to nations all the way around the ocean basin. 2. A broad pattern of signal radiation from a satellite that covers one-third of the earth's surface. (Type of beam used by INTELSAT satellites.)

Global Systems for Mobile Communications—Originally called the Groupe Speciale Mobile. Abbreviated GSM. The digital cellular standard for Europe.

globule test—A solderability test specifically for component leads. The time required for a globule of solder to completely wet around a component lead is measured and recorded and then compared against a known standard. This particular test requires a certain amount of human evaluation.

glossmeter—A photoelectric instrument for determining the gloss factor of a surface (i.e., the ratio of light reflected in one direction to the light reflected in all directions).

glow discharge—A discharge of electricity through a gas in an electron tube. It is characterized by a cathode glow resulting from a space potential much higher than the ionization potential of the gas in the vicinity of the cathode.

glow-discharge microphone—A microphone in which the sound waves cause corresponding variations in the current forming a glow discharge between two electrodes.

glow-discharge tube—A gas tube that depends for its operation on the properties of a glow discharge.

Glow-discharge tube.

glow-discharge voltage regulator—A gas tube used for voltage regulation. The resistance of the gas

within the tube varies in step with the voltage applied across the tube.

glow lamp—1. A lamp containing a small amount of gas or vapor. Current between the two electrodes ionizes the gas and causes the lamp to glow but does not provide rectification. Neon gives a red-orange glow, mercury vapor a blue glow, and argon a purple glow. 2. Gas-discharge tube serving as a concentrated source of light whose brightness varies in proportion to current flow. When an audio-frequency signal is combined with the lamp current, the brightness of the glow discharge varies according to the audio-frequency signal variations. 3. Glow-discharge type of tube whose light brightness is proportional to the current passing through the tube; used for photographic recording of facsimile signals. 4. A lamp in which the ionization of the inert gas contained in it produces a glow in the space close to the negative electrode.

glow potential—The voltage at which a glow discharge begins in a gas-filled electronic tube as the voltage is gradually increased.

glow-tube rectifier—Also called a point-plane rectifier. A cold-cathode gas-discharge tube that provides a unidirectional current flow.

glow switch—An electron tube used in some fluorescent-lamp circuits. It contains two bimetal strips that are closed when heated by the glow discharge.

glue-line heating—An arrangement of electrodes designed to heat a thin film of material having a high loss factor between alternate layers of materials having a low loss factor.

g_m —Symbol for the mutual conductance or transconductance of a vacuum tube.

G-M counter—Abbreviation for Geiger-Mueller counter.

GMT or **Gmt**—Abbreviation for Greenwich mean time.

gobo—A dark mat used to shield the lens of a television camera from stray lights.

gold—A very soft, ductile material that is noted for its resistance to corrosive media. It is used primarily as a coating or plating.

gold-bonded diode—A semiconductor diode in which a preformed whisker of gold contacts an n-termination substrate as the junction is formed by millisecond electrical pulses.

gold doping—1. A technique used to control the lifetime of minority carriers in a diffused-mesa transistor. Gold is diffused into the base and collector regions to reduce the storage time. 2. A process sometimes used in the manufacture of integrated circuits, in which gold is diffused into the semiconductor material, resulting in higher operating speeds.

gold-leaf electroscope—An apparatus comprising two pieces of gold leaf joined at their upper ends and suspended inside a glass jar. When a charge is applied to the terminal connected to the leaves, they spread apart due to repulsion of the like charges on them.

Goldschmidt alternator—An early radio transmitter. It is a rotating machine employing oscillating circuits in connection with the field and the armature to introduce harmonics in the generated fundamental frequency. Interaction between the stator and rotor harmonics gives a cumulative effect and thereby provides very high radio frequencies.

goniometer—1. In a radio-range system, a device for electrically shifting the directional characteristics of an antenna. 2. An electrical device for determining the azimuth of a received signal by combining the outputs of

individual elements of an antenna array in certain phase relationships.

go/no-go test—A test that determines whether a unit under test is functioning in accordance with specifications, but does not perform any diagnostic tests to determine the cause of an incorrect output.

Gopher—1. A menu-based system for organizing and distributing information on the Internet, which allows users to browse or download files and directories. Simpler to use but similar in functionality to FTP. A key feature is the ability to include menu items that connect the user to other Gopher servers. Developed at the University of Minnesota, and partially named after their mascot. 2. Internet databases that can be accessed by the World Wide Web (WWW) as well as other Gopher clients.

Gopherspace—All Gopher sites are at some point interconnected, and this network is known as Gopherspace. Gopherspace results from the ability to link different Gopher sites together.

goto circuit—A circuit capable of sensing the direction of current. It can be used in majority logic circuits, in which the output is either positive or negative depending on whether the majority of the inputs is positive or negative.

goto pair—Two tunnel diodes connected in series in a way such that one is in the reverse tunneling region when the other is in the forward conduction region. This arrangement is used in high-speed gate circuits.

governed series motor—A motor used with teletypewriter equipment. It has a governor for regulating the speed.

governor—1. A motor attachment that automatically controls the speed at which the motor rotates. 2. The equipment that controls the gate or valve opening of a prime mover.

GPI—Abbreviation for ground-position indicator.

GPIB—Abbreviation for general-purpose interface bus. Also called HPIB (Hewlett Packard interface bus) and, more formally, IEEE Standard 488.2 interface. 1. A byte-serial bus created to interconnect instruments and computers. 2. The standard interface hardware used in computer systems. It has been adopted by the IEEE as the IEEE-488 instrument bus standard, which is intended to define standard interface techniques for limited transmission distances (up to 20 meters). It is an eight-bit wide digital interface applicable for both programmable and nonprogrammable components. The bus provides compatibility between interfacing components, offers noise immunity, and covers the use of interfacing with special connectors.

grabber hand—An on-screen image of a hand that is controlled with a mouse.

graceful degradation—A computer programming technique whose purpose is to prevent catastrophic system failure by permitting the machine to operate, although in a degraded mode, in spite of failures or malfunctions in several integral units or subsystems.

graded-base transistor—*See* diffused-base transistor.

graded-core glass optical fiber—For most applications of high information rate (bandwidth), a fiber that has a core in which the highest optical density is at the center. Optical density decreases with distance from the center until it is the same as the cladding. That is, the optical density of the core is graded downward from the center of the core to the edge of the core, at which point it is equal to the cladding optical density.

graded filter—A power-supply filter in which the output stage of a receiver or audio amplifier is connected at or near the filter input so that the maximum available

dc voltage will be obtained. The output stage has low gain; therefore, ripple is not too important.

graded-index fiber—1. An optical fiber made with a refractive index that gets progressively lower as the diameter increases. 2. An optical fiber in which the index of refraction varies in the fiber, usually decreasing approximately parabolically from the center to the surface. 3. A fiber whose index of refraction decreases with increasing radial distance from the center of the core.

graded insulation—A combination of insulation proportioned so as to improve the distribution of the electric field to which the combination is subjected.

graded-junction transistor—*See* rate-grown transistor.

graded thermoelectric arm—A thermoelectric arm having a composition that changes continuously in the direction of the current.

gradient—The rate at which a variable quantity increases or decreases. For example, potential gradient is the difference of potential along a conductor or through a dielectric.

gradient-index fibers—Optical fibers that keep a pulse of photons together for a longer time by gradually bending the photon paths back to the core of the fiber before they get all the way to the surface. While the weaving photon travels a longer distance than those traveling in a straight line down the center of the fiber, the glass in the core is treated to slow down the light. This keeps the packets of photons in proximity for a longer time. This fiber is being used in almost all phone company installations today.

gradient meter—*See* generating electric field meter.

gradient microphone—A microphone in which the output rises and falls with the sound pressure. *See also* pressure microphone.

grain growth—The increase in the size of the crystal grains in a glass coating or other material over a period.

gram—A unit of mass and weight in the metric system. Letter symbol: g.

gramme ring—A ring-shaped iron armature around which the coils are wound. Each turn is tapped from the inside diameter of the ring to a commutator segment.

grandfather cycle—The period during which magnetic-tape records are retained before reusing so that records can be reconstructed in the event of loss of information stored on a magnetic tape.

grand-scale integration—*See* GSI.

granular carbon—Small particles of carbon used in carbon microphones.

granularity—A characteristic of the output data of a measuring instrument. The measure of granularity is the smallest increment of the output data when it is in a digital form. The smallest increment is also called least count.

graph—A pictorial presentation of the relationship between two or more variables.

graphechon—A specially designed electron memory tube, based on iconoscope principles, in which electrical signal information is stored and recovered at different

Graphechon.

scanning rates. It is used in radar and computer applications.

graphic—A symbol produced by a process such as handwriting, drawing, or printing.

graphical analysis—The use of diagrams and other graphic methods to obtain operating data and answers to scientific or mathematical problems.

graphical data operations—Manipulations that a system can perform on points, lines, symbols, angles, and other graphical representations. These operations include delete, insert, replace, move, rotate, expand, contract, and extrapolate.

graphical language—A programming language that expresses programs in a graphical form resembling flowcharts.

graphic equalizer—1. An equalizer that functions simultaneously at a number of preset frequencies, any of which may be boosted or cut independently of all others. Often done at standard 1, $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{6}$ octave center frequencies. Graphic equalizers are generally peaking-type equalizers. 2. A multiband equalizer whose controls are sliders, so that their settings can be seen as a rough graph of their frequency response characteristics. 3. Tone control device that uses separate adjustments to cut or boost different frequencies within the audio band. A graphic equalizer provides greater control over tone than single-knob tone controls.

graphic instrument—*See* recording instrument.

graphics—1. In communications systems, an information mode in which intelligence is reproduced by use of a graphic system (a variation of facsimile). 2. Nonvoice analog information modes and devices such as facsimile and television. 3. Using computer technology to create a drawing that is usually displayed on a terminal or plotter.

graphics board—A hardware add-on that boosts a computer's graphics capabilities. Common graphics adapters include CGA, EGA, VGA, and Super VGA.

graphic symbol—An electronic circuit diagram symbol formed using one or more basic elements such as lines, circles, arcs, and squares. The meaning of a symbol is not changed by its orientation, although some symbols are generally shown in one direction by convention. Line width and symbol size do not affect a graphic symbol's meaning.

graphic tablet—A surface through which coordinate points can be transmitted by identification with a cursor or stylus.

graphic terminal—1. A cathode-ray-tube display. 2. An XY plotter.

graphite—A finely divided carbon used as a lubricant and in the construction of some carbon resistance elements. The most common use is in so-called lead pencils.

grass—The pattern produced by random noise on an A-scope; it appears as closely spaced, sharp, constantly moving pulses on the base line. *See also* random noise.

grasshopper fuse—A small fuse with a spring-loaded fusible wire. When the wire fuses to open the circuit, the spring shows a visible signal and closes an auxiliary circuit to actuate an alarm.

graticule—A calibrated screen placed in front of a cathode-ray tube for measurement purposes.

grating—A device for spreading out light or other radiation. It consists of narrow parallel slits in a plate or narrow parallel reflecting surfaces made by ruling grooves on polished metal. The slits or grooves break up the waves as they emerge. *See also* ultrasonic cross grating; ultrasonic space grating.

grating reflector—An antenna reflector consisting of an openwork metal structure that resembles a grating.

Gratz rectifier—An arrangement of two rectifiers per phase connected into a three-phase bridge circuit to provide full-wave rectification.

gravity—The force that tends to pull bodies toward the center of the earth, thereby giving them weight. *See also* g.

gravity cell—A primary cell in which two electrolytes are kept separated by differences in specific gravity. It is a modification of the Daniell cell and is now obsolete.

gray body—A radiating body whose spectral emissivity remains the same at all wavelengths. It is in constant ratio of less than unity to the radiation of a blackbody radiator at the same temperature.

Gray code—1. A positional binary number notation in which any two numbers whose difference is 1 are represented by expressions that are the same except in one place or column and differ by only one unit in that place or column. 2. A numeric code composed of a number of bits, assigned in such a way that only one bit changes at each increment (or decrement). 3. A modified binary code. Sequential numbers are represented by binary expressions in which only one bit changes at a time; thus, errors are easily detected.

Gray-code test patterns—A sequence of input patterns in which only one input pin changes state at each test step.

gray image—Any image composed of the full spectrum of gray shades ranging from black to white.

gray scale—1. A series of regularly spaced tones ranging from white to black through intermediate shades if gray used as a reference scale for control purposes in photography or TV. 2. The discrete levels of the video signal between reference-black and reference-white levels.

gray-scale capability—The ability to accurately reproduce different light levels. At present there are several standards for judging gray-scale display. Some define each light "level" that makes up the scale as the brightness change discernible by the eye (typically a 3- to 5-percent change). Another standard, less subjective, defines gray scale as the difference in brightness required to produce a specified density change on processed film.

gray scale image—An image consisting of an array of pixels that can have more than two values.

great manual—Also called the accompaniment manual or lower manual. In an organ, the keyboard normally used for playing the accompaniment to the melody.

green-gain control—A variable resistor used in the matrix of a three-gun color television receiver to adjust the intensity of the green primary signal.

green gun—The electron gun whose beam, when properly adjusted, strikes only the green phosphor dots in the color picture tube.

green restorer—A dc restorer used in the green channel of a three-gun color-television picture-tube circuit.

green video voltage—The signal voltage that controls the grid of the green gun in a three-gun picture tube.

Greenwich civil time—*See* universal time.

Greenwich mean time—Abbreviated GMT or Gmt. The mean solar time at the meridian of Greenwich (zero longitude). It is used as a world-wide reference time. Also called zulu time, because of the Z time zone. This widely used standard time reference is equivalent to EDT plus 4 hours, EST or CDT plus 5 hours, CST or MDT plus 6 hours, MST or PDT plus 7 hours, and PST plus 8 hours.

Gregorian antenna—A satellite antenna with a sub-reflector mounted near the focal point, for improved focusing of satellite signals.

grid—1. An electrode having one or more openings for the passage of electrons or ions. *See also* control grid; screen grid; shield grid; space-charge grid; suppressor grid. 2. An interconnected system in which high-voltage, high-capacity backbone lines overlay and are connected with networks of lower voltages. 3. A two-dimensional network consisting of a set of equally spaced parallel lines superimposed upon another set of equally spaced parallel lines so that the lines of one set are perpendicular to the lines of the other, thereby forming square areas. The intersections of the lines provide the basis for an incremental location system. 4. An arrangement of electrically conducting wire, screen, or tubing placed in front of doors or windows or both, which is used as a part of a capacitance sensor. 5. A lattice of wooden dowels or slats concealing fine wires in a closed circuit that initiates an alarm signal when forcing or cutting the lattice breaks the wires. Used over accessible openings. Sometimes called a protective screen. 6. A screen or metal plate, connected to earth ground, sometimes used to provide a stable ground reference for objects protected by a capacitance sensor. If placed against the walls near the protected object, it prevents the sensor sensitivity from extending through the walls into areas of activity. 7. Network of uniformly spaced points on an input device used for locating position.

grid battery—Sometimes called a C battery. A source of energy for supplying a bias voltage to the grid of a vacuum tube.

grid bearing—A bearing made with the reference line to grid north.

grid bias—Also called C-bias. A constant potential applied between the grid and cathode of a vacuum tube to establish an operating point.

grid-bias cell—A small cell used in a vacuum-tube circuit to make the grid more negative than the cathode. It provides a voltage, but cannot supply an appreciable amount of current.

grid blocking—1. Blocking of capacitance-coupled stages in an amplifier because of an accumulated charge on the coupling capacitor as the result of current flow during the reception of large signals. 2. A method of keying a circuit by application of a negative grid voltage several times during key-up conditions; when the key is down, the blocking bias is removed, and normal current through the keyed circuit is restored.

grid cap—At the top of some vacuum tubes, the terminal that connects to the control grid.

grid capacitor—A capacitor in parallel with the grid resistor or in series with the grid lead of a tube.

grid-cathode capacitance—Capacitance between the grid and the cathode in a vacuum tube.

grid characteristic—The curve obtained by plotting grid-voltage values of a vacuum tube as abscissas against grid-current values as ordinates on a graph.

grid circuit—The circuit connected between the grid and cathode and forming the input circuit of a vacuum tube.

grid-circuit tester—A tester designed to measure the grid resistance of vacuum tubes without discriminating between the type or polarity of impedance.

grid clip—A spring clip used for making a connection to the top-cap terminal of some vacuum tubes.

grid-conductance—The in-phase component of the alternating grid current divided by the alternating grid voltage, all other electrode voltages being maintained constant.

grid control—Control of the anode current of an electron tube by means of changes in the voltage between the control grid and cathode of the tube.

grid-controlled mercury-arc rectifier—A mercury-arc rectifier employing one or more electrodes exclusively for controlling start of the discharge.

grid-controlled rectifier—A triode mercury-vapor rectifier tube in which the grid determines the instant at which plate current starts to flow during each cycle, but does not determine how much current will flow.

grid-control tube—A mercury-vapor-filled thermionic vacuum tube with an external grid control.

grid current—The current that flows in the grid-to-cathode circuit of a vacuum tube. It is usually a complex current made up of several currents having a variety of polarities and impedances.

grid detection—Detection by rectification in the grid circuit of a vacuum tube.

grid-dip meter—A multiple-range oscillator incorporating a meter in the grid circuit to indicate grid current. The meter is so named because its reading dips (reads a lower grid current) whenever an external resonant circuit is tuned to the oscillator frequency.

Grid-dip meter.

grid dissipation—The power lost as heat at the grid of a tube.

grid-drive characteristic—The relationship between the electrical or light output of an electron tube and the control-electrode voltage measured from cutoff.

grid driving power—The average product of the instantaneous value of grid current and the alternating component of grid voltage over a complete cycle.

grid emission—Electron or ion emission from the grid of an electron tube.

grid-glow tube—A glow-discharge cold cathode tube in which one or more control electrodes initiate the anode current but do not limit it except under certain conditions.

gridistor—A field-effect transistor that uses the principle of centripetal striction and has a multichannel structure, combining the advantages of both field-effect transistors and minority-carrier injection transistors.

grid leak—A high resistance connected across the grid capacitor or between the grid and cathode. It provides a direct-current path, to limit the accumulation of a charge on the grid.

grid-leak capacitor—A small capacitor connected in a vacuum-tube grid circuit, together with a resistor, to produce grid bias.

grid-leak detector—A triode or multielectrode tube in which rectification occurs because of electron current through a high resistance in the grid circuit. The voltage associated with this flow appears in amplified form in the plate circuit.

grid limiting—The use of grid-current bias derived from the signal, through a large series grid resistor, in order to cut off the plate current and consequently level the output wave for all input signals above a critical value.

grid locking—Faulty tube operation in which excessive grid emission causes the grid potential to become continuously positive.

grid modulation—Modulation produced by application of the modulating voltage to the control grid of any tube in which the carrier is present. Modulation in which the grid voltage contains externally generated pulses is called grid-pulse modulation.

grid neutralization—A method of neutralizing an amplifier. A portion of the grid-to-cathode alternating-current voltage is shifted 180° and applied to the plate-to-cathode circuit through a neutralizing capacitor.

grid north—An arbitrary reference direction used with the grid system of navigation.

grid-plate capacitance—The direct capacitance between the grid and plate of a vacuum tube.

grid-plate transconductance—Mutual conductance, which is the ratio of a plate-current change to the grid-voltage change that produces it.

grid-pool tank—A grid-pool tube having a heavy metal envelope somewhat resembling a tank in appearance.

grid-pool tube—A gas-discharge tube having a mercury-pool cathode, one or more anodes, and a control electrode or grid to control the start of current. *See also* excitron; ignitron.

grid-pulse modulation—Modulation produced in an amplifier or oscillator by application of one or more pulses to a grid circuit.

grid pulsing—Method of controlling the operation of a radio-frequency oscillator. The oscillator-tube grid is biased so negatively that oscillation occurs, even at full plate voltage, except when this negative bias is removed by application of a positive voltage pulse to the grid.

grid resistor—A general term that denotes any resistor in the grid circuit.

grid return—An external conducting path for the return of grid current to the cathode.

grid suppressor—A resistor, sometimes connected between the control grid and the external circuit of an amplifier, to prevent parasitic oscillations caused by stray-capacitance feedback.

grid swing—The total variation in grid-to-cathode voltage from the positive peak to the negative peak of the applied-signal voltage.

grid-to-cathode capacitance—The direct capacitance between the grid and cathode of a vacuum tube.

grid-to-plate capacitance—Designated C_{gp} . The direct capacitance between the grid and plate in a vacuum tube.

grid-to-plate transconductance—The mutual conductance, or ratio of plate-current to grid-voltage changes, in a vacuum tube.

grid voltage—The voltage between the grid and cathode of a tube.

grid-voltage supply—The means for supplying, to the grid of an electron tube, a potential that is usually negative with respect to the cathode.

grille cloth—A loosely woven fabric that is virtually transparent to sound, often stretched across the opening

in a speaker enclosure that seats the radiating side of the speaker.

grommet—An eyelet of rubber or neoprene placed in a hole in sheet metal, such as a terminal entrance, to insulate and protect wires that pass through.

groove—In mechanical recording, the track inscribed in the record by a cutting or embossing stylus, including undulations or modulations caused by vibration of the stylus. In stereo discs its cross section is a right-angled triangle, with each side at a 45° angle to the surface of the record; information is cut on both sides of the groove. In a long-playing record, groove dimensions could be: width 2.5 mils (63.5 μm); depth 1 mil (25.4 μm), and pitch 250–350 groove revolutions per inch (98–138 groove revolutions per centimeter).

groove angle—In disc recording, the angle between the two walls of an unmodulated groove in a radial plane perpendicular to the surface of the recording medium.

groove shape—In disc recording, the contour of the groove in a radial plane perpendicular to the surface of the recording medium.

groove speed—In disc recording, the linear speed of the groove with respect to the stylus.

groove velocity—The speed with which the record groove moves under the cartridge. An lp record rotates at a constant 33 1/3 rpm with grooves cut at diameters that decrease gradually from 11 1/2 to 4 3/4 inches (29.2 to 12.1 cm). Groove velocity therefore ranges from 20 in/s (50.8 cm/s) at the outside of the record to 8.3 in/s (21.1 cm/s) in the innermost groove.

gross information content—A measure of the total information, including redundant portions, contained in a message. It is expressed as the number of bits or hartleys necessary to transmit the message with specified accuracy by way of a noiseless medium without coding.

ground—1. A connection to the earth for conducting electrical current to and from the earth. 2. The voltage reference point in a circuit. There may or may not be an actual connection to earth, but it is understood that a point in the circuit said to be at ground potential could be connected to earth without disturbing the operation of the circuit in any way. 3. A point in an electrical system that has zero voltage. Usually, the chassis of an electrical component is at ground potential and thus serves as the return path for signals as well as for power circuits. The shield in coaxial signal cable is, or should be, at ground potential to avoid hum pickup. Ground also designates the earth, literally, which is used as a return path for radio waves from an antenna. In British terminology *earth* is used to designate all ground connections. 4. A conducting connection through which a circuit or electrical equipment is connected to the earth or to a conducting body that is at earth potential. A ground may be accidental or intentional. 5. To connect to a ground. 6. Connection (intentional or accidental) between an electrical circuit and the earth or its electrical equivalent.

ground absorption—The loss of energy during transmission because of the radio waves dissipated to ground.

ground bus—A conductor, usually large-diameter wire, that connects a number of points to one or more ground electrodes.

ground check—Also known as base-line check. 1. A procedure followed prior to the release of a radiosonde in order to obtain the temperature and humidity correction for the radiosonde system. 2. Any instrumental check prior to the ground launch of an airborne experiment.

ground clamp—A clamp used for connecting a grounding conductor (ground wire) to a grounded object such as a water pipe.

Ground clamps.

ground clutter—The pattern produced on the screen of a radar indicator by undesired ground return.

ground conductor—A conductor in a transmission cable or line that is grounded.

ground conduit—A conduit used solely to contain one or more grounding conductors.

ground control—To guide or direct an aircraft or missile by control exercises from the ground.

ground-controlled approach—Abbreviated GCA. 1. The radar system developed to give direction, distance, and elevation along a fixed approach path to an airport. The ground controller at the radarscope communicates instructions to the pilot to direct the aircraft along the approach line. 2. Technique or procedure for "talking down," through the use of both surveillance and precision approach radar, an aircraft during its approach so as to place it in a position for landing.

ground-controlled interception—Abbreviated GCI. A radar system used for directing an aircraft to intercept enemy aircraft.

ground controller—Aircraft controller stationed on the ground. Generic term applied to the controller in ground-controlled approach, ground-controlled interception, etc.

ground current—Current in the earth or grounding connection.

ground detector—1. An instrument or equipment that indicates the presence of a ground on a normally ungrounded system. 2. Device that indicates ground faults in electrical circuits.

ground distance—The great-circle component of distance from one point to another at mean sea level.

grounded—1. Connected to the earth, to a rod or pipe that makes a good electrical connection with the earth, or to some conduction body in place of the earth. 2. A system, circuit, or apparatus that is provided with a ground.

grounded-base amplifier—See common-base amplifier.

grounded cable bond—A cable bond used for grounding the armor and/or sheaths of cables.

grounded capacitance—In a system having several conductors, the capacitance between a given conductor and the other conductors when they are connected together and to ground.

grounded-cathode amplifier—The conventional amplifier circuit. It consists of a tube amplifier in which

the cathode is at ground potential at the operating frequency. The input is applied between the control grid and ground, and the output load is between the plate and ground.

grounded circuit—1. A circuit in which one conductor or point (usually the neutral conductor or neutral point of transformer or generator windings) is intentionally grounded (earthed) either solidly or through a grounding device. 2. A circuit that is connected to earth at one or more points.

grounded-collector amplifier—See common-collector amplifier.

grounded conductor—A conductor that is intentionally grounded, either directly or through a current-limiting device.

grounded dielectric constant—The dielectric constant of the earth at a given location.

grounded-emitter amplifier—See common-emitter amplifier.

grounded-gate amplifier—A FET amplifier circuit in which the gate electrode is connected to ground. The input signal is applied to the source electrode, and the output is taken from the drain electrode.

grounded-grid amplifier—An electron-tube amplifier circuit in which the control grid is at ground potential at the operating frequency. The input is applied between the cathode and ground, and the output load is between the plate and ground. The grid-to-plate impedance of the tube is in parallel with the load, instead of acting as a feedback path.

Grounded-grid amplifier.

grounded-grid triode—A type of triode designed for use in a grounded-grid circuit.

grounded-grid triode circuit—A circuit in which the input signal is applied to the cathode and the output is taken from the plate. The grid is at rf ground and serves as a screen between the input and output circuits.

grounded-grid triode mixer—A triode in which the grid forms part of a grounded electrostatic screen between the anode and cathode. It is used as a mixer for centimeter wavelengths.

grounded neutral—The neutral wire in an electrical power system metallically connected to ground.

grounded outlet—An outlet equipped with a receptacle of the polarity type having, in addition to the current-carrying contacts, one ground contact, which can be used for the connection of an equipment-grounding conductor.

grounded parts—Parts of a completed installation that are so connected that they are substantially at the same potential as the earth.

grounded-plate amplifier—Also called cathode follower. An electron-tube amplifier circuit in which the

plate is at ground potential at the operating frequency. The input is applied between the control grid and ground, and the output load is between the cathode and ground.

grounded system—A system of electrical conductors in which at least one conductor or point (usually the middle wire or neutral point of transformer or generator windings) is intentionally grounded, either solidly or through a current-limiting device.

ground environment—1. The environment surrounding and affecting a system or item of equipment that operates on the ground. 2. A system or part of a system that functions on the ground. 3. The aggregate of all ground-installed equipment that makes up a communications-electronics system, facility, station, set, etc. 4. The portion of an air-defense system that provides for the detection, surveillance, and control of airborne objects. It includes ground-based facilities and overwater facilities, such as picket vessels and airborne early warning and control aircraft.

ground-equalizer inductors—Relatively low-inductance coils inserted in the circuit to one or more of the grounding points of an antenna to obtain a desired distribution of the current to the various points.

ground fault—1. An unintentional electrical path between a part operating normally at some potential to ground and ground. 2. A current leak from the hot side of the line through a path that bypasses the load to ground. This current leak causes an imbalance between the hot and neutral wires to the load.

ground fault current—A fault current that flows to ground rather than between conductors.

ground-fault interrupter—A device that senses the imbalance caused by a ground fault with a differential-current transformer. Two primary windings, each in series with one side of the line, are wound on the transformer core. Equal currents in both lines cancel each other to produce no transformer signal in a third sensor winding. However, current imbalance generates a sensor output, which is amplified to trip a circuit-opening device. *See also* current limiter.

ground-gate amplifier—A FET amplifier circuit in which the gate electrode is connected to the ground. The input signal is applied to the source electrode, and the output is taken from the drain electrode.

ground gating—The conversion of pulse-amplitude modulated signals at a telemetry ground station to 50-percent duty-cycle signals.

ground grid—A system of grounding electrodes interconnected by bare cables buried in the earth to provide lower resistance than a single grounding electrode.

ground indication—An indication of the presence of a ground on one or more of the normally ungrounded conductors of a system.

grounding—1. Connecting to ground, or to a conductor that is grounded. 2. A means of referencing electrical circuits to the well-bonded equipotential surface. 3. A connection between the electrical system and the earth to prevent shock. Ground wires are usually bare; grounding connections are normally green in color. A safety measure to avoid electric shock.

grounding conductor—A conductor that, under normal conditions, carries no current but serves to connect exposed metal surfaces to earth ground, to prevent hazards in case of breakdown between current-carrying parts and the exposed surfaces. The connector, if insulated, is colored green with or without a yellow stripe.

grounding connection—A connection used to establish a ground, consisting of a grounding conductor, a grounding electrode, and the earth surrounding the electrode.

grounding electrode—A conductor or network of conductors, usually embedded in the earth, used for maintaining ground potential on conductors connected to it or for dissipating into the earth any current conducted to it.

grounding outlet—An alternating-current receptacle that has a third contact connected to ground. Used with three-wire plugs and cords to ground portable electrical tools and appliances safely.

grounding plate—An electrically grounded metal plate on which a person stands in order to discharge any static electricity that may be picked up by his or her body.

grounding switch—A form of air switch for connecting a circuit or apparatus to ground.

grounding transformer—A transformer intended primarily for the purpose of providing a neutral point for grounding purposes.

ground insulation—The major insulation used between a winding and structural parts at ground potential.

ground junction—In a semiconductor, a junction formed during the growth of a crystal from a melt.

ground level—*See* ground state.

ground loop—1. An unwanted feedback condition in which power current in a single ground wire causes instability or errors. 2. A potentially detrimental condition produced when two or more points in an electrical system that are nominally at ground potential are connected by a conducting path. The term usually is applied when, because of improper design or by accident, unwanted noise signals are generated in the common return of relatively low-level signal circuits by the return currents or by magnetic fields produced by relatively high-power circuits or components. 3. The electrical path between two separate grounds. 4. A condition occurring when two or more paths to ground exist and a voltage is induced unequally in these paths, causing interference like hum, buzz, or noise. 5. A term used to describe situations occurring in ground systems in which a difference in potential exists between two ground points due to the resistance of ground conductors.

ground-loop disturbances—Detrimental interference formed when two or more points in an electrical system that are nominally at ground are connected by a conducting path such that either or both are not at the same ground potential.

ground lug—A lug for connecting a grounding conductor to a grounding electrode.

ground mat—A system of bare conductors, on or below the surface of the earth, connected to a ground or ground grid to provide protection from dangerous touch voltage.

ground noise—In recording and reproducing, the residual noise in the absence of a signal. It is usually caused by dissimilarities between the recording and reproducing media, but may also include amplifier noise such as from a tube or noise generated in resistive elements at the input of the reproducer amplifier system.

ground-noise margin—The voltage that may be applied at the ground connection of a logic circuit without causing the circuit to malfunction. It is usually measured by increasing the static ground voltage on a single gate until the logic fails to operate properly.

ground outlet—An electrical outlet equipped with a polarized receptacle that has, in addition to the current-carrying contacts, a grounded contact to which can be connected an equipment-grounding conductor.

ground plane—1. Copper or brass sheet used in interference testing to simulate missile, aircraft, or vehicle frame or skin so that actual installation and grounding conditions may be approximated. 2. A conductor layer,

or portion of a conductor layer, used as a common reference point for circuit returns, shielding, or heat sinking. 3. Expanded copper mesh that is laminated into some flat cable constructions as a shield. May be supplied with one, two, or no drain wires. A common ground electrical path for power and/or signals.

ground-plane antenna—A vertical antenna combined with a turnstile element to lower the angle of radiation. It has a concentric base support and a center conductor that place the antenna at ground potential, even though located several wavelengths above ground.

Ground-plane antenna.

ground plate—A plate of conductive material buried in the earth to serve as a grounding electrode.

ground-position indicator—Abbreviated GPI. A dead-reckoning computer, similar to an air-position indicator, with provision for taking drift into account.

ground potential—Zero potential with respect to ground or the earth.

ground power cable—A cable assembly fitted with appropriate terminations to supply power to an aircraft from a ground power unit.

ground protection—Protection of a circuit by means of a device that opens the circuit when a fault to ground occurs.

ground protective relay—A device that functions on failure of the insulation of a machine, transformer, or other apparatus to ground, or on flashover of a dc machine to ground.

ground range—In range measurements related to airborne radar, the distance on the surface of the earth between the object under consideration and a point directly below the aircraft that carries the radar.

ground-reflected wave—1. In a ground wave, the component reflected from the earth. 2. A radio wave reflected one or more times from the earth's surface before reaching the point of reception.

Ground-reflected waves.

ground resistance—1. The opposition of the earth to the flow of current through it. Its value depends on

the nature and moisture content of the soil; the material, composition, and physical dimensions of the connection to earth; and the electrolytic action present. 2. The ohmic resistance between a grounding electrode and a remote or reference grounding electrode so spaced that their mutual resistance is essentially zero.

ground return—1. In radar, the echoes reflected from the earth's surface and fixed objects on it. 2. A lead from an electronic circuit, antenna, or power line to ground.

ground-return circuit—A circuit that has a conductor (or two or more in parallel) between two points and which is completed through ground or the earth. A circuit using the earth as one side of the complete circuit.

ground rod—1. A steel or copper rod driven into the earth to make an electrical contact with it. 2. A long metal rod that is driven into the ground near an antenna installation and to which are attached the grounding wires from the mast and antenna discharge unit to discharge static electricity to ground before it can enter and damage the TV receiver.

ground-scatter propagation—Multihop ionospheric propagation of radio waves along other than the great-circle path between the transmitting and receiving points. Radiation from the transmitter is returned from the ionosphere to the surface of the earth, from which it is then scattered in many directions.

ground shift—The variation in signal amplitude at different grounding points because of a voltage drop along a ground line.

ground speed—In navigation, the speed of a vehicle with reference to ground.

ground state—Also called ground level. The lowest energy level or state of an atom or atomic system; all other states of the system are called excited states.

ground support cable—Cable construction, usually rugged and heavy, for use in ground support control or power systems.

ground-support equipment—All ground equipment that is part of a complete weapons system and that must be furnished to ensure complete support of the weapons system.

ground system of an antenna—The portion of an antenna system that includes an extensive conducting surface, which may be the earth itself, and those parts of the antenna closely associated with that surface.

ground-to-air communication—One-way communication from ground stations to aircraft.

ground wave—1. A radio wave that travels along the earth's surface rather than through the upper atmosphere. 2. That portion of a radio wave traveling between transmitting and receiving antennas that is associated with currents induced in the ground or water surface of the earth. Important only below about 10 MHz.

ground wire—1. A conductor leading to an electric connection with the earth. 2. A heavy copper conductor, usually insulated, that is used to connect protectors or other equipment to a ground rod or cold water pipe.

group—1. In carrier telephony, a number of voice channels multiplexed together and treated as a unit. Commonly, a group contains 12 channels, each with a bandwidth of 4 kHz, frequency multiplexed and occupying the band from 60 to 180 kHz. 2. The second-highest stratum of an organizational hierarchy, usually identifying departments, divisions, or regions.

group busy tone—A high tone fed to the jack sleeves of an outgoing trunk group to serve as an indication that all trunks in the group are busy.

group channel—A unit or method of organization on telephone carrier (multiplex) systems. A full group is a channel equivalent to 12 voice-grade channels (48 kHz).

A half group has the equivalent bandwidth of 6 voice-grade channels (24 kHz). (When not subdivided into voice facilities, group channels can furnish high-speed data communication.)

group delay—Also called envelope delay. 1. The delay in transmission of information modulated on a carrier. 2. Distortion resulting from nonuniform speed of transmission of the various frequency components of a signal through a transmission medium; specifically, the propagation delay of a lower frequency is different from that of a higher frequency. This creates a time-related delay-distortion error.

grouped-frequency operation—A method in which different frequency bands are used for channels in opposite directions in a two-wire carrier system.

group frequency—The number of sets or groups of waves passing a given point in one second.

grouping—1. Nonuniform spacing between the grooves of a disc recording. 2. Periodic error in the spacing between recorded lines in a facsimile system.

grouping circuits—Circuits used to interconnect two or more positions of a switchboard so that one operator may handle the several positions from one operator's set.

group loop—A source of interference when a system is grounded improperly at several points.

group mark—A mark used to identify the beginning or the end of a set of data, which could include words, blocks, or other items.

group modulation—The process by which a number of channels, already separately modulated to a specific frequency range, are again modulated to shift the group to another range.

Group I fax—An analog facsimile device that transmits or receives a standard page in four to six minutes. Group I machines are no longer being manufactured and are rarely in use today.

group technology—Facilitation of processing through combination of similar parts into production families.

Group III fax—The standard for current facsimile devices. Most current facsimile systems are digital devices offering operating speeds of one minute or less. When equipped with automatic speed recognition, these systems can be compatible with Group I and II units, although a number of the lower-cost models are strictly Group III compatible. Machines that can recognize speed automatically can select the fastest speed available when sending to or receiving from Group I or Group II devices.

Group II fax—An analog device that transmits or receives a page in two or three minutes. These systems offer some data-compression techniques for faster transmission and can be compatible with Group I devices. Like the Group I units, Group II models are not actively marketed today.

group velocity—1. Of a traveling plane wave, the velocity of propagation of the envelope delay is approximately constant. It is equal to the reciprocal of the envelope delay per unit length. (Group velocity differs from phase velocity in a medium in which the phase velocity varies with the frequency.) 2. The velocity of the envelope of an electromagnetic wave as it travels in a medium, usually identified with the velocity of energy propagation.

groupware—Software that is designed to be used by a group of people working on the same information, whether in the same room, building, or across town or the globe.

Grove cell—A primary cell with a platinum electrode submerged in an electrolyte of nitric acid within a porous cup, surrounded by a zinc electrode in an electrolyte of

sulfuric acid. This cell normally operates on a closed circuit.

growler—1. An electromagnetic device consisting essentially of two field poles arranged as in a motor, energized with ac and used for locating short-circuited coils in a generator or motor armature. A growling noise indicates a short-circuited coil. 2. An electromagnetic device for magnetizing or demagnetizing objects.

grown-diffused transistor—A transistor made by combining the diffusion and double-doped techniques. Suitable n- and p-type impurities are added simultaneously to the melt while the crystal is being grown. Subsequently, the base region is formed by diffusion as the crystal grows.

grown junction—The boundary between p- and n-type semiconducting materials. It is produced by varying the impurities during the growth of a crystal from the melt. Such junctions have strong rectifying properties, the forward current being obtained when p is positive to n.

grown-junction photocell—A photodiode made of a small bar of semiconductor material that has a pn junction at right angles to its length and an ohmic contact at each end of the bar.

grown-junction transistor—A transistor in which junctions are formed by adding impurities to the melt while the crystal is being grown.

grown-junction wafer—A semiconductor wafer on which pn junctions are formed during manufacture.

grown semiconductor junction—A junction formed during the growth of a crystal from a melt.

G-scan—See G-display.

G-scope—See G-display.

GSI—Abbreviation for grand-scale integration. Monolithic integrated circuits with a typical complexity in excess of 1000 or more gates or gate equivalent circuits.

GSO—Abbreviation for geostationary satellite orbit. A circular orbit 35,863 km above the earth, in the plane of the earth's equator, in which a satellite revolves around the earth in the same time that the earth rotates on its axis; thus, the satellite appears approximately stationary over one point on the earth.

Geostationary satellites.

GTAW—Abbreviation for gas tungsten arc welding. See also TIG.

GTO SCR—Abbreviation for gate turn-off SCR. A silicon-controlled rectifier whose output-current switching can be turned off by a voltage at the gate.

guard—A mechanism to terminate program execution (real or simulated) upon access to data at a specified memory location. Used in debugging.

guard arm—1. A crossarm placed across and in line with cable to protect it from damage. 2. A crossarm placed over wires to prevent other wires from falling into them.

guard band—1. Also called interference guard band. A frequency band left vacant between two channels to safeguard against mutual interference. 2. The unused chip surface area that, by virtue of physical spacing, serves to isolate functional elements in a printed circuit or an integrated circuit. Also refers to the consideration given instrumentation precision in electrical testing. 3. The unused bandwidth separating channels to prevent crosstalk.

guard channel—1. Unused portions of the frequency spectrum that are located between program channels to prevent adjacent channel interference. *See also* guard band. 2. One or more auxiliary parallel processing channels to control the main processing channel in order to reject interference that is partly in, but not centered on, the main channel. Guard channels may be displaced in time (range), Doppler frequency, carrier frequency, or angle.

guard circle—An inner concentric groove on disc records. It prevents the pickup from being thrown to the center of the record and possibly damaged.

guarded input—An input that has a third terminal that is maintained at a potential near the input-terminal potential for a single-ended input, or near the mean input potential for the differential input. It is used to shield the entire input circuit.

guarded motor—An open motor in which all openings given direct access to live or rotating parts (except smooth shafts) are limited in size by the structural parts or by screens, grilles, expanded metal, etc., to prevent accidental contact with such parts. Such openings shall not permit the passage of a cylindrical rod $\frac{1}{2}$ inch (12.7 mm) in diameter.

guard frequency—The frequencies between subchannels in frequency-division multiplexed systems used to guard against subchannel interference.

guarding—1. The introduction of conducting surfaces at critical points in a circuit to intercept and divert leakage currents that otherwise would cause undesired effects or measurement errors. 2. A method of protecting the inputs to a high-gain op amp by surrounding the input terminals with a conducting ring of printed circuit board conductors. This isolates the inputs from potential leakage currents from other parts of the circuit. 3. The use of special circuitry, insulated from ground, to provide freedom from adverse effects of leakage currents. The stray current is bypassed through a noncritical path so that it does not affect the accuracy of measurement. Guarding is especially important when measuring low voltages and when measuring high-value resistances, particularly when high humidity causes a reduction in normally high insulation resistance.

guard relay—A relay used in the linefinder circuit to prevent more than one linefinder from being connected to any line circuit when two or more line relays are operated simultaneously.

guard ring—1. A metal ring placed around a charged terminal or object to distribute the charge uniformly over the surface of the object. 2. A ring-shaped electrode intended to limit the extent of an electric field, as, for instance, in elimination of the fringe effect at the edges of the plates of a capacitor.

guard-ring capacitor—A capacitor with parallel electrodes, one of which is surrounded by a ring held at the potential of that electrode in order to reduce the edge effect.

guard shield—An internal floating shield surrounding the input section of an amplifier. Effective shielding results only when the absolute potential of the guard is stabilized relative to the incoming signal.

guard-well capacitor—A primary standard capacitor, fixed or variable, for values of capacitance below 1 picofarad. The guard ring forms a well in which a Pyrex disk is mounted for the accurate location of the electrode assembly.

guard wire—A grounded wire used frequently where high-tension lines cross a thoroughfare. Should a line break, it will contact the guard wire and be grounded.

Gudden-Pohl effect—The momentary illumination produced when an electric field is applied to a phosphor previously excited by ultraviolet radiation.

guidance—Control of a missile or vehicle from within by a person, a preset or self-reacting automatic device, or a device that reacts to outside signals.

guidance system—A system that measures and evaluates flight information, correlates it with target data, converts the resultant into the parameters necessary to achieve the desired flight path, and communicates the appropriate commands to the flight-control system.

guidance tapes—Magnetic or paper tapes that are placed in a missile or computer and that contain previously entered information necessary for directing the missile to the selected target.

guide—In a tape recorder, a grooved or flanged pin or roller that guides the tape in a straight line between the reels and the heads, to keep it perfectly in line with the pole pieces.

guided ballistic missile—A ballistic missile that is guided during the powered portion of the trajectory and follows a free ballistic path during the remainder.

guided clip—*See* guided probe.

guided missile—An unmanned vehicle moving above the surface of the earth, the trajectory or flight path of which is capable of being altered by an external or internal mechanism.

guided probe—1. A fault-isolation technique in which the test system automatically displays the next mode or IC that the operator should probe or clip. The system leads the operator along a path back from a faulty output pin to the location of the fault. A software algorithm uses stored interconnection information and expected responses at each node to determine the next node to be probed. 2. A hand-held probing device (single-point or multipin clip) guided by an operator with instructions from a computer-controlled algorithm.

guided propagation—A type of radiowave propagation in which radiated rays are bent excessively by refraction in the lower layers of the atmosphere. This bending creates an effect much as if a duct or a waveguide has been formed in the atmosphere to guide part of the radiated energy over distances far beyond normal range.

guided spark—An electrical discharge between two electrodes that has its path guided or constrained by the presence of a dielectric material or a gas jet.

guided wave—A wave in which the energy is concentrated near a boundary (or between substantially parallel boundaries) separating materials of different properties. The direction of propagation is parallel to the boundary.

guide pin—A pin or rod that extends beyond the mating faces of a connector in such a way that it guides the closing or mating of the connector and ensures proper engagement of the contacts.

guide wavelength—*See* waveguide wavelength.

Guillemin line—A special type of artificial transmission line or pulse-forming network used in radar sets to control the duration of the pulses. It generates a nearly square pulse for use in high-level pulse modulation.

guillotine capacitor—A translatory motion tuning capacitor consisting of a pair of stators and a sliding plunger in place of a rotor.

gullwing—A common lead form used to interconnect surface-mounted packages to a printed circuit board.

gun-directing radar—Radar used for directing antiaircraft or similar artillery fire.

Gunn diode—1. A tiny wafer of n-type gallium arsenide consisting of a thin active layer of n-type gallium arsenide grown on a low-resistivity substrate of the same material. The substrate is bonded to the anode terminal of the encapsulation, and the other face of the wafer has an evaporated cathode contact connected by a bonded gold wire. The diode has no pn junction and cannot be used for rectification. When a few volts dc are applied to make the anode positive with respect to the cathode, the current that flows is dc with superimposed pulses. 2. A microwave diode that exhibits negative resistance arising from the bulk negative differential conductivity that occurs in several compound semiconductors, such as gallium arsenide, and that operates at a frequency determined by the transit time of charge bunches that are formed due to this negative differential conductivity.

Gunn effect—Current oscillations that occur at an rf rate when an electric field of about 3000 V/cm is applied to a short (127 μm or 0.005 in or less) specimen of n-type gallium arsenide. This effect takes place because electrons under the influence of sufficiently high fields are transferred from high- to low-mobility valleys in the conduction band of GaAs.

Gunn oscillator—An oscillator in which the active element is a Gunn diode operating in the negative resistance mode. This type of oscillator is one of the simplest means of generating microwave signals because only a microwave-tuned circuit, Gunn diode, bias network, and low-voltage power supply are required. Presently available units are restricted to operation above 4 GHz, and have dc to rf conversion efficiencies of less than 10 percent.

gutta-percha—A natural vegetable gum, similar to rubber, used principally as insulation for wire and cables.

guy ring—A circular metal collar with attachment holes (eyes) that is slipped on and clamped to an antenna mast. Guy wires are then attached to the mast through the holes in the guy ring.

guy wire—A wire used to brace the mast or tower of a transmitting or receiving antenna system.

Guy wire.

gyrator—1. A two-port circuit element that exhibits a 180° differential, or nonreciprocal, phase shift. The

guillotine capacitor — gyroscopic action

gyrator circuit symbol indicates that an rf signal transmitted from port 1 to port 2 will undergo a 180° phase shift relative to an rf signal transmitted in the reverse direction. 2. A negative-impedance device that can change the sign of a reactance, thus allowing a capacitor to act as an inductor. Usually consists of a ferrite section in a waveguide. Through the use of such a device, some of the shortcomings of inductors can be eliminated. These shortcomings are large physical size, low Q , nonlinearity, and interwinding capacitance. A properly designed gyrator will provide a synthetic inductor with Q , wide bandwidth, inductance value independent of frequency, and good stability. Filters for frequencies up to 50 kHz can be designed using gyrators. 3. A device providing 180° phase shift in one direction relative to the other direction of signal passage.

Circuit.

Symbol.

Gyrator.

gyro—Abbreviation for gyroscope.

gyrocompass—See gyroscope.

gyrofrequency—The natural frequency at which charged particles rotate around the lines of force of the earth's magnetic field. For electrons, it is 700 to 1600 kilohertz; for ions, it is in the audio-frequency range.

gyromagnetic—The magnetic properties of rotating electric charges, such as electrons spinning within atoms.

gyromagnetic effect—The change in the angular momentum of a body as a result of being magnetized, arising as a result of the fact that the magnetic moments of its electrons are associated with their spins or orbital angular momentum.

gyropilot—See autopilot.

gyroscope—Abbreviated gyro. A rotating device whose axle will maintain a constant direction, even though the earth is turning under it. It consists of a wheel mounted so that its spinning axis is free to rotate around either of two other axes perpendicular to itself and each other. When its axle is pointed north, it can be used as a gyrocompass.

gyroscopic action—An action that causes a mass to turn on an axis perpendicular to the applied torque and to the axis of spin.

gyrostabilized platform — *See* stable platform.

gyrotron — A microwave vacuum tube based on the interaction between an electron beam and microwave fields in which coupling is achieved by the cyclotron resonance condition. This type of coupling allows the beam and microwave circuit dimensions to be large compared with a wavelength. Thus, the power density problems encountered

in conventional traveling-wave tubes and klystrons at millimeter wavelengths are avoided in the gyrotron.

G–Y signal — In color television, the green-minus-luminance signal, representing primary green minus the luminance, or Y, signal. It is combined with a luminance, or Y, signal outside or inside the picture tube to yield a primary green signal.

H

H—1. A radar air-navigation system using an airborne interrogator to measure the distance from two ground responder beacons. *See also* shoran. 2. Symbol for heater, magnetic field strength, or henry.

hacker—1. A person with computer expertise intrinsically interested in the exploration of computer systems and their capabilities. 2. A person who accesses computer systems without authorization. 3. One who deliberately tries to penetrate the security of other computers. 4. A skilled computer enthusiast who is obsessed with learning about programming and exploring the capabilities of computer systems. 5. A person who gains unauthorized access to a computer system.

hacking—Using a microcomputer system or terminal to bypass the security of a large computer system.

hairpin pickup coil—A hairpin-shaped, single-turn coil for transferring UHF energy.

hairpin tuning bar—A sliding hairpin-shaped metal bar inserted between the two halves of a doublet antenna to vary its electrical length.

halation—1. Distortion seen as blurred images and caused by reflection of the image rays off the back of a fluorescent screen that is too thick. 2. The spreading of light in a photographic emulsion outside the intended area of exposure by reflection from the rear surface of the material supporting the emulsion; this is distinguished from the diffusion that takes place within the emulsion layer. 3. A glow or diffusion that surrounds a bright spot on a television picture tube screen. A defect in picture tube quality is indicated. 4. In a cathode-ray tube, the glow surrounding a bright spot that appears on the fluorescent screen as the result of the screen's light being reflected back by the front and rear surfaces of the tube's face.

half-add—In a computer, an operation that is performed first in carrying out a two-step binary addition. It consists of addition of corresponding bits in two binary numbers, with any carry information being ignored. *See also* exclusive OR.

half adder—1. A circuit that will accept two binary input signals and produce corresponding sum and carry outputs. So called because, above the first order, two half adders per order are required when adding two quantities. 2. Building-block circuit used in digital computers. A combination of logic gates adds two bits and delivers an answer—two bits called sum and carry. Half adders can be combined to add numbers of any length. Two half adders make up a full adder. 3. A logic element that adds two input bits, but does not have provision for adding the carry from a previous addition. *See also* full adder.

half cell—An electrode, submerged in an electrolyte, for measuring single electrode potentials.

half cycle—The time interval required for the operating frequency to complete one-half, or 180°, of its cycle.

Circuit.

B	A	CARRY	SUM
0	0	0	0
0	1	0	1
1	0	0	1
1	1	1	0

Truth table.

Symbol.

Half adder.

half-digit—In digital meters provided with 100 percent overranging, an additional most-significant digit provided at the left of the readout, capable of displaying the numeral 1 when the measurement exceeds the full-scale range.

half duplex—1. A communication system in which information can be transmitted in either direction, but only in one direction at a time. 2. In communications, pertaining to an alternate independent transmission made in one direction at a time. 3. A mode of data transmission capable of communicating in one of two directions, but in only one direction at a time. 4. Refers to a communication channel that can receive and transmit, but not simultaneously.

half-duplex circuit—Abbreviated HDX. A circuit that permits one-direction electrical communications between stations. Technical arrangements may permit operation in either direction, but not simultaneously. Therefore, this term is qualified by one of the following suffixes: s/o for send only, r/o for receive only, or s/r for send or receive.

half-duplex modem—A modem with a single wire pair that can transmit in both directions but not simultaneously.

half-duplex operation—A duplex telegraph system capable of operating in either direction, but not in both simultaneously.

half-duplex repeater—A duplex telegraph repeater provided with interlocking arrangements that restrict the transmission of signals to one direction at a time.

half-hertz transmission—A data transmission and control system in which synchronized sources of 60-Hz power are used at transmitting and receiving ends. Either of two relays at the receiver can be actuated by proper choice of the half-hertz polarity of the transmitter power supply.

half-life—1. The time in which half the atoms in a radioactive substance decay. In the first half-life interval, the amount of radioactive material left unchanged is one-half the original amount; in the next half-life interval, half of the remaining amount, or one-fourth of the original amount, remains. Thus, by determining the remaining radioactivity of a fossil and comparing it with the half-life of the material, scientists can estimate the age of the fossil. The half-life of various materials varies greatly—from millions of a second to billions of years. 2. Time required for a source to decay to one-half its initial millicurie value. Typical values are Cs-137, 30 years; Co-60, 5.3 years; Sr-90, 28 years; Kr-85, 10.7 years; Am-241, 457 years; and Ra, 1622 years.

half-nut—A feed nut that engages half the circumference or less of a lead screw, so that it can be withdrawn from the lead screw to stop the lateral scanning movement.

half-power frequency—Either a high frequency or a low frequency at which the output of an amplifier, network, transducer, etc., falls to one-half (± 3 dB) of its maximum or nominal response.

half-power point—On an amplitude response characteristic or other curve of the magnitude of a network quantity versus frequency, distance, angle, or other variable, the point that corresponds to half the power of a neighboring point having maximum power.

half-power width of a radiation lobe—In a plane containing the direction of the maximum of the lobe, the full angle between the two directions in that plane in which the radiation intensity is one-half the maximum value of the lobe.

half-shift register—1. A logic circuit that consists of a gated input storage element with or without an inverter. 2. A logic device equivalent of half of a full master-slave flip-flop.

half step—*See* semitone.

half tap—A bridge that can be placed across conductors without disturbing their continuity.

half-time emitter—A device that produces synchronous pulses midway between the row pulses of a punched card.

half-tone characteristic—In facsimile, the fidelity of the recorded density shadings in comparison with the

original transmitted subject copy. Also used to express the relationship between the facsimile signal and the subject or recorded copy.

half track—*See* two track.

half-track recorder—*See* dual-track recorder.

half-track tape—Also called two-track tape. Quarter-inch magnetic tape on which half the width of the tape is used for one sound path. Such a tape provides stereo in one direction of tape travel, or mono sound in both directions.

half-track tape-recording format—A professional tape recording standard format in which independent tracks (channels) are recorded in the same direction. Two tracks on $\frac{1}{4}$ -inch (6.35-mm) wide tape or four tracks on $\frac{1}{2}$ -inch (12.7-mm) wide tape or eight tracks on 1-inch (25.4-mm) wide tape or 16 tracks on 2-inch (50.8-mm) wide tape are used.

half wave—A wave with an electrical length of half a wavelength.

half-wave antenna—An antenna having an electrical length equal to half the wavelength of the signal being transmitted or received.

half-wave dipole—A straight, ungrounded antenna measuring substantially one-half wavelength.

half-wave rectification—1. The production of a pulsating direct current by passing only half the input cycle of an alternating current. The other half is blocked by the rectifier. 2. The process of blocking the negative half cycle of current of an alternating input. This is accomplished by a single diode.

half-wave rectifier—A rectifier utilizing only one-half of each cycle to change alternating current into pulsating direct current.

half-wave transmission line—A piece of transmission line having an electrical length equal to half the wavelength of the signal being transmitted or received.

half-wave vibrator—A vibrator used mainly in battery-operated mobile power supplies. It has only one pair of contacts, and supplies an intermittent unidirectional current at its output (usually connected to a half-wave rectifier).

half word—A nonbroken sequence of bits or characters that makes up half a computer word and that can be addressed as a unit.

Hall constant—The constant of a proportionality in the equation for a current-carrying conductor in a magnetic field. The constant is equal to the transverse electric field (Hall field) divided by the product of the current density and the magnetic field strength. The sign of the majority carrier can be inferred from the sign of the Hall constant.

Hall effect—1. In a current-carrying semiconductor bar located in a magnetic field that is perpendicular to the direction of the current, the production of a voltage perpendicular to both the current and the magnetic field. 2. The description given to the following phenomenon:

Half-wave rectifier.

when a conductor, through which a current is flowing, is placed in a magnetic field, a potential difference is generated between the two opposed edges of the conductor in the direction mutually perpendicular to both the field and the conductor.

Hall-effect generator—Also called Hall sensor.

1. A magnetic sensor using the Hall effect to give an output voltage proportional to magnetic field strength. 2. A device made of compounds such as indium arsenide, indium antimonide, or silicon that produces a useful Hall-effect potential. Its output is proportional to magnetic induction through the semiconductor.

Hall-effect modulation—Use of a Hall-effect multiplier as a modulator to produce an output voltage proportional to the product of two input voltages or currents.

Hall-effect switch—A keyboard switch that incorporates an IC chip containing a Hall generator, trigger circuit, and amplifier. Depressing the key moves the magnet shunt member across the chip. This increases the magnetic flux through the chip and causes the analog voltage generated by the Hall element to switch the trigger circuit to its on state.

Hall generator—A thin wafer of semiconductor material used for measuring ac power and magnetic field strength. Its output voltage is proportional to the current passing through it times the magnetic field perpendicular to it.

Hall generator.

Hall mobility—The product of conductivity and the Hall constant for a conductor or semiconductor. It is a measure of the mobility of the electrons or holes in a semiconductor.

Hall sensor—See Hall-effect generator.

halo—1. The undesirable ring of light around a spot on the fluorescent screen of a cathode-ray tube. 2. The appearance of a blank border around unusually bright objects in a televised scene.

halogen—A general name applied to four chemical elements, fluorine, chlorine, bromine, and iodine, that have similar chemical properties.

halogen quenching—A method of quenching the discharge in a counter tube by the introduction of a small quantity of one of the halogens.

halt—The state in which a computer stops and does nothing.

ham—Also called amateur. Slang for a licensed radio operator who operates a station as a hobby rather than a business.

Hamming code—1. One of the error correction code systems used in data transmission. 2. A forward error correction technique named for its inventor. It corrects single-bit errors. 3. A seven-bit error-correcting computer code.

hand capacitance—The capacitance introduced when one's hand is brought near a tuning capacitor or other insufficiently shielded part of a tuned circuit.

handheld—An amateur radio transceiver small enough to be carried in one hand (often abbreviated HT). Typically, amateur handhelds are for VHF/UHF use.

Handie-Talkie—Trade name of the Motorola Communications Division for a two-way radio small enough to be carried in one's hand.

handler—Also called device handler. 1. A section of a computer program used to control or communicate with an external device. 2. A software routine that controls the operation of a peripheral.

handoff—The transfer of a cellular phone call to a new cell, designed to be transparent to the cellular phone user. During a cellular conversation, when the user reaches the edge of the service area of a cell, computers in the network assign another tower in the next cell to provide the phone with continuing service.

hand receiver—An earphone held to the ear by hand.

hand reset—A relay in which the contacts must be reset manually to their original positions after normal conditions are resumed.

handset—1. A telephone-type receiver and transmitter mounted on a single frame. 2. That portion of the telephone containing the transmitter and receiver that is hand-held when the telephone is in use. Consists of a receiver and transmitter about 6 inches (15.2 cm) apart at the ends of a common handle, connected by an electrical cord to the handset mounting. Sometimes includes a dial or Touchtone pad.

handset telephone—See hand telephone set.

hands-free telephone—A desk telephone containing a microphone and voice-switched amplifiers with a separate speaker unit, permitting telephone conversation without use of a hand-held handset.

handshake—1. An interface procedure that is based on status/data signals that assure orderly data transfer as opposed to asynchronous exchange. 2. In communications, a preliminary exchange of predetermined signals performed by modems and/or terminals to verify that communication has been established and can proceed.

handshake cycle—The process whereby digital signals effect the transfer of each data byte across the interface by means of an interlocked sequence of status and control signals. "Interlocked" denotes a fixed sequence of events in which one event in the sequence must occur before the next event may occur.

handshaking—1. A process in which predetermined arrangements of characters are exchanged by the receiving and transmitting equipment to establish synchronization. 2. The exchange of predetermined signals between machines connected by a communications channel to assure each that it is connected to the other. May also include the use of passwords and codes by an operator. 3. A colloquial term that describes the method used by a modem to establish contact with another modem at the other end of a telephone line. Often used interchangeably with buffering and interfacing, but with a fine line of difference in which handshaking implies a direct package-to-package connection regardless of functional circuitry. 4. A CPU-terminal interface process that prevents overrun and ignores signaling. The transmitter sends a signal in response to a request from the receiver, which then sends an acknowledgment signal to the transmitter. 5. The exchange of predetermined signals for control purposes during establishment of a connection between two data sets or modems. 6. Refers to the sequence of signals exchanged when a connection is established between two modems or between a DCE

and a DTE. 7. Line-termination interplay to establish a data-communication path. 8. Exchange of predetermined signals establishing contact between two data sets. *See* answerback.

hand telephone set—Also called a handset telephone. A telephone set having a handset and a mounting that supports the handset when not in use.

hangover—1. Also called tailing. The smeared or blurred bass notes reproduced by a poorly damped speaker or one mounted in an improperly vented enclosure. 2. In television, overlapping and blurring, in the direction opposite to subject motion, of successive frames as a result of improper transient response. 3. In facsimile, distortion that occurs when the signal changes from maximum to minimum at a slower rate than required, with the result that there is tailing on the lines in the copy.

hangup—1. A condition in which the central processor of a computer is trying to perform an illegal or forbidden operation or in which it is continually repeating the same routine. 2. Commutation failure in which the load controlled by a solid-state relay cannot be turned off because the thyristor current does not reach zero or stay near zero for long enough for the gate circuit to regain control.

hard—1. Indicating an electron tube that has been evacuated to a high degree. 2. Indicating X-rays of relatively high penetrating power.

hard automation—Production technique in which equipment is engineered specifically for a unique manufacturing sequence. Hard automation implies programming with hardware in contrast to soft automation, which uses software or computer programming.

hard contacts—Any type of physical switch contacts. Contrasted with electronic switching devices, such as triacs and transistors.

hard contact switch—A keyboard switch in which switching action is accomplished by the movement of one gold-plated bar against another at right angles—the classic cross-bar switching. The knife-edge contact area is extremely small (typically about 9×10^{-6} square inch or 5.8×10^{-5} cm²), resulting in an extremely high contact pressure (typically about 5000 psi or 3.45×10^7 Pa).

hard copy—Also hardcopy. 1. Typewritten or printed characters on paper produced by a computer at the same time information is copied or converted into machine language that is not easily read by a human. 2. A printed copy of a machine output. 3. Data in a permanent and tangible form, such as printed, punched, or even handwritten. 4. The printed original copy of a message. 5. Output in printed form, such as the output of a teleprinter. Used as an adjective, signifies that the device involved produces such output. 6. Computer or machine output in a permanent, visually readable form. For example, printed reports, listings, translation lists, documents, and summaries. 7. A tangible, printed copy of a message, such as that obtained from a teletypewriter or computer, as opposed to a volatile display on a video terminal. *See also* printout.

hard-copy printer—An automatic device that produces intelligible symbols in a permanent form.

hard disk—A rigid disk of magnetic or magnetically coated material, rotating in a sealed housing and used as a recording and playback system for computer programs and data. Hard disks can store far more information than floppy disks and can write and read information more quickly.

hard-drawn copper wire—Copper wire that is not annealed after work hardening during drawing, thus providing increased tensile strength.

hardened links—1. Transmission links for which special construction or installation is necessary to assure

a high probability of survival under nuclear attack.

2. Passive protection to aid survival.

hardener—Also called curing agent. A chemical added to a thermosetting resin to stimulate curing.

hard error—1. An error in magnetic media, electromechanical devices, or electronics that is repeatable. 2. Semiconductor memory condition in which the cell or cells will not properly store data under any condition, test, or operation.

hard firing—A condition in which the gate signal of an SCR is several times the dc triggering current and in which the rise time of the gate current is short relative to the turn-on time.

hard limiting—The condition in which limiting takes place for at least 20 dB into the signal noise.

hardline—1. The intelligence link between two objects that consists of a wire or wires, as opposed to a radio or radar link. 2. A low-loss coaxial cable that has a continuous hard metal shield instead of a conductive braid around the outer perimeter.

hard magnetic materials—Magnetic materials that are not easily demagnetized.

hardness—1. Referring to X-rays, the quality that determines their penetrating ability. The shorter the wavelength, the harder and hence more penetrating they are. 2. Property of an installation, facility, transmission link, or equipment that will prevent an unacceptable level of damage.

hardness tester—Equipment for determining the force required to penetrate the surface of a solid.

hard rubber—A material formerly widely used for insulation. It is formed by vulcanizing rubber at high temperature and pressure to give it the desired hardness.

hard scrambling—An encryption method that uses proprietary, highly secure technology (i.e., digital), such as that used by *VideoCipher II*.

hard-sectored—A disk whose sectors are marked by holes in the disk itself.

hard solder—Solder composed principally of copper and zinc. It must be red hot before it will melt. Hard soldering is practically equivalent to brazing.

hard soldering—Process of joining two metals by utilizing an alloy with a melting temperature higher than 800°F (427°C). *See* soft soldering.

hard tube—A high-vacuum electronic tube.

hardware—1. Mechanical, magnetic, electrical, or electronic devices; physical equipment from which a system is fabricated. (Contrasted with software.) 2. Particular circuits or functions built into a system. 3. The physical components of a computer or a system. (Software is the term used to describe the programs and instructions for a computer.) 4. The electronic components, such as gates, inverters, and storage devices, that make up a system (as opposed to software and firmware). 5. Items of equipment used in a communications or data processing system. 6. The physical equipment components of a computer system, e.g., mechanical, magnetic, electrical, or electronic devices.

hardware buffer—A register or set of registers used to store information temporarily, usually to act as a transition medium between a fast and a slow device.

hardware independent—Computer software that is not dependent on a certain make of computer.

hardwire—A colloquialism meaning a circuit evidencing dc continuity.

hardwired—1. Electrical devices interconnected through physical wiring. 2. The implementation of a function with logic gates; i.e., hardware as opposed to software. 3. Electronic-programming technique using soldered connections; hence, not readily reprogrammable. 4. Physically

interconnected, usually for a specific purpose. Hardwired logic is essentially unalterable. 5. Pertaining to the physical connection of two pieces of electronic equipment by means of a cable or wires.

hard-wired logic—1. A group of solid-state logic modules mounted on one or more circuit boards and interconnected by electrical wiring. The logic control functions are determined by the way in which the modules are interconnected. (As contrasted with a programmable controller or microprocessor, in which the logic is in program form.) 2. A group of solid-state logic modules mounted on one or more circuit boards and interconnected by electrical wiring. The logic control functions are determined by the way in which the modules are interconnected. 3. A group of logic circuits permanently interconnected to perform a special function. Permanently assigned device addresses, memory block assignments, and interrupt vector addresses.

hard X-rays—Highly penetrating X-rays, as distinguished from less penetrating, or soft, X-rays.

harmful interference—Any radiation or any induction that disrupts the proper functioning of an electromagnetic system.

harmonic—A sinusoidal wave having a frequency that is an integral multiple of the fundamental frequency. For example, a wave with twice the frequency of the fundamental is called the second harmonic.

harmonica bug—See infinity device.

harmonic analysis—1. A method of identifying and evaluating the harmonics that make up a complex waveform of voltage, current, or some other varying quantity. 2. The expression of a given function as a series of sine and cosine terms that are approximately equal to the given function, such as a Fourier series. 3. Defining a complex wave as the sum of several harmonics of the fundamental wave, each harmonic having a specified magnitude and phase.

harmonic analyzer—Also called harmonic-wave analyzer. A mechanical or electronic device for measuring the amplitude and phase of the various harmonic components of a wave from its graph.

harmonic antenna—An antenna whose electrical wavelength is an integral multiple of a half wavelength.

harmonic attenuation—Elimination of a harmonic frequency by using a pi network and tuning its shunt resistances to zero for the frequency to be eliminated.

harmonic component—Of a periodic quantity, any one of the simple sinusoidal quantities of the Fourier series into which the periodic quantity may be resolved.

harmonic content—1. The degree of distortion in the output signal of an amplifier. 2. The components remaining after the fundamental frequency has been removed from a complex wave.

harmonic conversion transducer—A conversion transducer in which the useful output frequency is a multiple or submultiple of the input frequency.

harmonic detector—A voltmeter circuit that measures only a particular harmonic of the fundamental frequency.

harmonic distortion—1. The production of harmonic frequencies at the output by the nonlinearity of a transducer when a sinusoidal voltage is applied to the input. The amplitude of the distortion is usually a function of the amplitude of the input signal. 2. The voltages of harmonics resulting from amplitude distortion expressed as a percentage of the voltage of the fundamental. A common measurement is total harmonic distortion (THD), in which the fundamental of a very low distortion sine-wave test signal is removed by a steep notch filter. The summed harmonics that remain are then measured as a voltage and expressed as a percentage (or dB value) of the voltage of

Harmonic content, 1.

the fundamental at the required test power of the amplifier. (When measured in this manner, the term THD is not really correct since the distortion also has the amplifier noise added to it within the test passband. The correct term is *distortion factor*.) 3. The sum of all signals in an output that are multiples of the input signal frequencies (harmonics). Their intensities are expressed as a percentage of the total output intensity. 4. The production of spurious frequencies, not present in the original sound, that are multiples of the original sound frequency. For example, a 100-Hz tone in the original may produce spurious tones at 200 Hz, 300 Hz, and so on. The result is an audible blurring or loss in the reproduced sound. Total harmonic distortion of no more than 1 percent is considered to be inaudible. 5. A data-communication-line impairment caused by erroneous frequency generation along the line.

harmonic filter—A combination of inductance and capacitance tuned to an undesired harmonic to suppress it.

harmonic generator—A vacuum tube transistor, or other generator operated so that it generates strong harmonics in the output.

harmonic interference—Interference between radio stations because harmonics of the carrier frequency are present in the output of one or more stations.

harmonic-leakage power (tr and pre-tr tubes)—The total radio-frequency power transmitted, through the fired tube in its mount, at other than the fundamental frequencies generated by the transmitter.

harmonic motion—Back and forth motion, such as that of a pendulum, in which the distance on one side of equilibrium always equals the distance of the other side; the acceleration is toward the point of equilibrium and directly proportional to the distance from it. Graphically, harmonic motion is represented by a sine wave.

harmonic oscillator—1. A circuit in which the oscillating frequency of the active device and the output frequency are not the same. For example, in a push-push configuration, each transistor oscillates at f_o but the output is combined to provide $2f_o$. 2. An oscillator whose output is very nearly a sine wave and whose output amplitude and frequency are very nearly constant.

harmonic producer—A tuning-fork-controlled oscillator used to provide carrier frequencies for broadband carrier systems. It is capable of producing odd and even harmonics of the fundamental tuning-fork frequency.

harmonic ringing — A system of selectively signaling several parties on a subscriber's line. The different rings are produced by currents that are harmonics of several fundamental frequencies.

harmonics — Undesired signals that appear at multiples (2, 3, etc.) of the desired fundamental frequency. They are produced by nonlinear amplifiers and can cause interference and other phenomena.

harmonic selective ringing — Selective ringing that employs currents of several frequencies and ringers, each tuned mechanically or electrically to the frequency of one of the ringing currents, so that only the desired ringer responds.

harmonic series of sounds — A series in which each basic frequency is an integral multiple of a fundamental frequency.

harmonic telephone ringer — A ringer that responds only to alternating current within a very narrow frequency band. A number of such ringers, each responding to a different frequency, are used in one type of selective ringing.

harmonic-wave analyzer — See harmonic analyzer.

harness — 1. Wires and cables arranged and tied together so they can be connected or disconnected as a unit. 2. A group of conductors laid parallel or twisted by hand, usually with many breakouts, laced or bundled together, or pulled into a rubber or plastic sheath. Used to interconnect electrical circuits.

hartley — In computers, a unit of information content equal to one decimal decision, or the designation of one of ten possible and equally likely values or states of anything used to store or convey information. One hartley equals $\log_2 10 = 3.23$ bits.

Hartley oscillator — An oscillator in which a parallel-tuned tank circuit is connected between the grid and plate of an electron tube or between the base and collector of a junction transistor, the inductive element of the tank having an intermediate tap at the cathode or emitter potential.

FET.

Bipolar transistor.

Hartley oscillator.

hash — 1. Electrical noise generated within a receiver by a vibrator or a mercury-vapor rectifier. See also grass. 2. A completely random interfering signal usually caused by arcing and occasionally by natural environmental disturbances.

hash-mark stripe — A noncontinuous helical stripe applied to a conductor for identification.

hash total — In a computer, a total for checking purposes. It is determined by adding all the digits or all the numbers in a particular field in a batch of unit records to be processed or manipulated, with no attention paid to the meaning or significance of the total. After processing, the hash total is recalculated and compared with the original total. If the two do not match, the original data has been changed in some way.

hat — To arrange a fixed number of symbols or groups of symbols in a random sequence, as if they had been drawn from a hat.

hatted code — A randomized code consisting of an encoding section. The plain-text groups are arranged in a significant order, accompanied by their code groups arranged in a random order.

haul — An arbitrary classification of telephone toll calls, as follows: short haul, less than 30 miles or 48 km; medium haul, 30 to 1000 miles or 48 to 1609 km; long haul, over 1000 miles or 1609 km.

Hay bridge — A four-arm, alternating-current bridge used for measuring inductance in terms of capacitance, resistance, and frequency. The arms adjacent to the unknown impedance are nonreactive resistors, and the opposite arm is composed of a capacitor in series with a resistor (unlike the Maxwell bridge, where it is in parallel). Usually the bridge is balanced by adjustment of the resistor, which is also in series with the capacitor and one of the nonreactive arms. The balance depends upon the frequency.

Hay bridge.

Hayes-compatible — A modem that recognizes the commands of a Hayes-manufactured modem.

hazard — See failure rate.

hazard rate — At a particular time, the rate of change of the number of items that have failed divided by the number of items surviving.

Hazeltine neutralizing circuit — An early form of neutralized radio-frequency amplifier circuit.

H-beacon — A nondirectional homing beacon with an output power of 50 to 2000 watts.

H-bend — Also called H-plane bend. In waveguide technique, a smooth change in the direction of the axis of

the waveguide. Throughout the change, the axis remains perpendicular to the direction of polarization.

HBO—Abbreviation for Home Box Office. The most popular pay-TV network, which is distributed on SAT-COM FI.

HCD—Abbreviation for hot-carrier diode.

H-display—Also called H-scan. In radar, a B-display modified to indicate the angle of elevation. The target appears as two closely spaced blips that approximate a short, bright line that slopes in proportion to the sine of the angle of target elevation.

HDLC—Abbreviation for high-level data link control. 1. A packet transmission protocol developed by the International Standards Organization (ISO) derived from IBM's Synchronous Data Link Control (SDLC). Messages are transmitted in units called frames, which can contain differing amounts of data but must be organized in a particular way. 2. A CCITT standard data-communication line protocol.

HDTV—See high-definition television.

HDX—See half-duplex circuit.

head—1. A device that reads, records, or erases data on a storage medium. For example, a small electromagnet used to read, write, or erase data on a magnetic drum or tape, or the set of perforating reading or marketing devices used for punching, reading, or printing on paper tape. 2. In a tape recorder, any device intended to change the magnetic state of the tape. Specialized types of heads are used for erasing the tape, recording a signal on it, and playing back the signal from it. In many recorders, the recording and playback functions are both performed (at different times) by the same head. 3. An electromagnetic device, usually consisting of a ring-shaped metal core wound with coils of wire, in which the continuity of the core is broken at one place, called the gap. Tape touches the head at the gap as it moves past it. A reproducing or playback head senses signals already magnetized (recorded) on tape and transforms them into electrical impulses that are then amplified and fed to a loudspeaker. A recording head accepts electrical signals and transforms them into magnetic impulses that are deposited on tape as it passes the head. Most cassette recorders use a single, combination record/playback head.

head alignment—Also called azimuth alignment. 1. Positioning the record/playback head on a tape recorder so that its gap is perpendicular to the tape. 2. On a VTR or VCR, the positioning of the audio or video heads so that they describe the current path at the correct angle across the videotape; heads that are out of alignment won't record or play back properly. 3. Adjustment of the recording or reproducing head so that it's at right angles to the longitudinal axis of tape. 4. Mechanical adjustment of the spatial relationships between the head gaps and the tape.

head amplifier—An audio-frequency amplifier mounted on or near the sound head of a motion-picture projector to amplify the extremely weak output of the phototube.

head demagnetizer—Also called degausser. 1. A special demagnetizer with elongated pole pieces enabling them to be brought into proximity to head surfaces for elimination of the built-up magnetic charge that develops over a period of time as a result of asymmetrical electrical input signals. 2. A device used to neutralize possible residual or induced magnetism in heads or tape guides.

headend—1. In a broadband transmission network, a group of active and/or passive components that translate one range of frequencies (Transmit) to a different frequency band (Receive); allows devices on a single cable network to send and receive signals without interference. 2. The master distribution center of a satellite TV

(SATV) system in which the incoming television signals from space and distant broadcast stations are received, amplified, and remodulated onto television channels for transmission down the SATV coaxial cable. 3. In a broadband local area network, the central location that has access to signals traveling in both inbound and outbound directions.

header—1. The part of a sealed component or assembly that provides support and insulation for the leads passing through the walls. 2. A feedthrough device that forms a conductive path through an insulating plate or surface. 3. The part of a semiconductor device package to which the actual chip or die is mounted. May consist of metal, ceramic, or one of a number of plastics, such as epoxy resin. 4. The portion of a device package from which the external leads extend. Examples include the TO-5 header and flat-pack case. 5. An information structure that precedes and identifies the information that follows, such as a block of bytes in communications, a file on a disk, a set of records in a database, or an executable program.

header card—A card containing information about the data in other cards that follow.

header record—A computer input record that contains common, constant, or identifying information for other records that follow.

head gap—A space inserted intentionally into the magnetic circuit of a magnetic recorder head to force or direct the flux into the recording medium.

head guy—The messenger cable and attachments placed so they pull toward the pole line.

heading—The direction of a ship, aircraft, or other object with reference to true, magnetic, compass, or grid north.

headlight—An aircraft radar antenna small enough to be housed in the wing, like an automobile headlight. The beam operates like a searchlight.

headphone—Also called a head receiver or phone. 1. A device held against the ear and having a diaphragm that vibrates according to current variations. It reproduces the incoming electrical signals as sound. Thus it permits private listening to a receiver amplifier or other device. 2. Small sound reproducers, superficially resembling miniature loudspeakers, set in a suitable frame for wearing about the head and listening to by close coupling to the ears. Recent headphones, improved greatly in fidelity, have become increasingly popular among audiophiles for private listening without disturbing others, as well as to prevent outside noises from interfering with the listening. Headphones are available in mono or stereo. 3. A telephone receiver held against the ear by a headband. See also headset.

head receiver—See headphone.

head room—1. The safety margin that is normally provided between the maximum recording level as indicated on a recorder level indicator and the actual point of severe tape overload. Most good recorders provide 6 to 8 dB of head room above the indicated 0-vu or normal maximum indicated recording level, to allow for the inability of the needle of the VU meter needle to respond fully to sudden, intense bursts of signal energy. 2. The difference between the nominal operating level and the maximum level at any point in a system or device. Usually expressed in decibels. 3. The margins between an actual signal operating level and the level that would cause substantial distortion. For a tape recorder this would be the level above 0 vu that gives a (specified) distortion.

headset—1. A headphone (or a pair of headphones) and its associated headband and connecting cord. 2. Small portable telephone receivers, usually in pairs, with a connecting clamp to support the phones against the ears,

for operators of receiving equipment. 3. An operator's head telephone set.

headset cord—A very flexible cord used for communication equipment, usually 24 AWG to 22 AWG multiconductor. Usually made with Buna insulation, rubber, or neoprene jacket; sometimes the outer jacket is a cotton braid. The conductor may be bare copper or cadmium bronze.

headshell—The end of a pickup arm where the cartridge fits. Sometimes bonded to the arm, though often detachable.

head stack—A group of two or more heads mounted in a single unit, used to provide multiple-track recording or reproduction.

head-to-tape contact—The degree to which the surface of the magnetic coating approaches the surface of the record or replay heads during normal operation of a recorder. Good head-to-tape contact minimizes separation loss and is essential in obtaining high resolution.

heap—A storage area used for dynamically allocated variables created by a running process without correlation to the static structure of the program.

hearing aid—A small audio-reproducing system for the hard of hearing. It consists of a microphone, amplifier, battery, and earphone and is used to increase the sound level normally received by the ear.

hearing loss—Also called deafness. 1. The hearing loss of an ear at a specified frequency—i.e., the ratio, expressed in decibels, of its threshold of audibility to the normal threshold. 2. The difference in level, expressed in decibels, between the weakest sound a particular human ear can hear and the weakest sound heard by an average, normal ear.

hearing loss for speech—The difference in decibels between the speech levels at which the average normal ear and the defective ear, respectively, reach the same intelligibility. It is often arbitrarily set at 50 percent.

heart pacer—*See* pacemaker.

heat aging—A test used to indicate the relative resistance of various insulating materials to heat degradation.

heat coil—A protective device that grounds or opens a circuit, or both, when the current rises above a predetermined value. A mechanical element moves when the fusible substance that holds it in place is heated above a certain point by current through the circuit.

heater—Also called filament. 1. An element that supplies the heat to an indirectly heated cathode. 2. A resistor that converts electrical energy into heat.

heater biasing—Application of a dc potential to the heater of a vacuum tube to eliminate diode conduction between it and some other element within the tube.

heater cord—Flexible stranded copper conductor, cotton wrapped, with rubber insulation and asbestos roving. For indoor use on household appliances.

heater current—The current flowing through a heater in a vacuum tube.

heater voltage—The voltage between the terminals of a heater.

heater-voltage coefficient—In a klystron, the frequency change per volt of heater voltage change when the reflector voltage is adjusted for the peak of a reflector voltage mode.

heat-eye tube—A cathode-ray tube powered by a midget generator. It is used as an infrared instrument that can "see" in the dark.

heat gradient—The difference in temperature between two parts of the same object.

heating effect of a current—Assuming a constant resistance, the amount of heat produced by the current through it. It is proportionate to the square of the current.

heating element—The wirewound resistor, terminals, and insulating supports used in electric cooking and heating devices.

heating pattern—In induction or dielectric heating, the distribution of temperature in a load or charge.

heating station—In induction or dielectric heating, the work coil or applicator and its associated production equipment.

heat loss—The loss due to conversion of part of the electric energy into heat.

heat of emission—Additional heat energy that must be supplied to an electron-emitting surface to keep its temperature constant.

heat of radioactivity—Heat generated by radioactive disintegration.

heat sealing—A method of joining plastic films by simultaneous application of heat and pressure to areas in contact. Heat may be supplied conductively or dielectrically.

heatseeker—A guided missile that uses an infrared sensor to detect and home in on an enemy target. The missile is guided by the high infrared emissions produced by a target, such as the heat from an aircraft or tank engine.

heat sensor—1. A sensor that responds to either a local temperature above a selected value or a local temperature increase that is at a rate of increase greater than a preselected rate. 2. A sensor that responds to infrared radiation from a remote source, such as a person.

heat shock—Test to determine stability of material by sudden exposure to a high temperature for a short period.

heat sink—1. A mounting base, usually metallic, that dissipates, carries away, or radiates into the surrounding atmosphere the heat generated within a semiconductor device. The package of the device often serves as a heat sink, but, for devices of higher power, a separate heat sink on which one or more packages are mounted is required to prevent overheating and consequent destruction of the semiconductor junction. 2. A mass of metal that is added to a device for the absorption or transfer of heat away from critical parts. Generally made from aluminum to achieve high heat conductivity and light weight, most heat sinks are of one-piece construction. They may also be designed for mounting on printed circuit boards. 3. A method used to transfer a rise in temperature. A metal plate or fin-shaped object with good heat-transfer efficiency that helps dissipate heat into the surrounding air, into a liquid, or into a larger mass. 4. A material capable of absorbing heat; a device utilizing such material for the thermal protection of components or systems. 5. A metal part with maximized surface areas to remove heat from electronic components, such as transistors, integrated circuit amplifiers, etc. 6. A mass of metal, often with fins, mounted on or under a circuit component that produces heat, such as a power transistor, silicon rectifier, etc. The heat sink absorbs and then radiates the heat to maintain a safe working temperature for the component.

Heat sink.

heat sink compound—A silicon compound filled with alumina or other heat-conductive oxide. Used to fill voids and irregularities in surfaces between two mating objects to permit optimum heat transfer.

heat soak—Heating a circuit over a period to allow all parts of the package and circuit to stabilize at the same temperature.

heat waves—Infrared radiation similar to radio waves but of a higher frequency.

heat-writing recorder—A type of stripchart recorder in which a heated stylus writes on a strip of chemically treated paper. The paper is discolored by the heat, and the path followed by the pen over the surface of the paper is thus made visible.

Heaviside-Campbell mutual-inductance bridge—A Heaviside mutual-inductance bridge in which one inductive arm contains a separate inductor that is included in the bridge arm during the first of a pair of measurements and is short-circuited during the second. The balance is independent of frequency. *See also* Heaviside mutual-inductance bridge.

Heaviside-Campbell mutual-inductance bridge.

Heaviside layer—Also called the Kennelly-Heaviside layer. The region of the ionosphere that reflects radio waves back to earth.

Heaviside mutual-inductance bridge—An alternating-current bridge normally used for the comparison of self- and mutual inductances. Each of the two adjacent arms contains self-inductance, and one or both of them have mutual inductance to the supply circuit. The other two arms normally are nonreactive resistors. The balance is independent of frequency.

heavy hydrogen—Another term for deuterium (${}_1\text{H}^2$) or tritium (${}_1\text{H}^3$).

hecto-—A prefix meaning 100.

hectometric wave—An electromagnetic wave between the wavelength limits of 100 and 1000 meters, corresponding to the frequency range 300 kHz to 3 MHz.

heelpiece—1. Part of a relay magnetic structure at the end of a coil, opposite the armature. It generally supports the armature and completes the magnetic path between it and the core of the coil. 2. The base of a relay, on which one or more contact spring assemblies are mounted, and to which the core of a relay is fastened.

Hefner lamp—A standard source that gives a luminous intensity of 0.9 candlepower.

HEI—Abbreviation for high-energy ignition. Conventional (General Motors) automotive electronic ignition

that replaces the distributor point system. Provides high voltage for high-energy spark timing control.

height control—In a television receiver, the adjustment that determines the amplitude of the vertical-scanning pulses and hence the height of the picture.

height finder—A radar that measures the altitude of an airborne object.

height input—Information regarding target height received by a computer from a height finder and relayed by way of a ground-to-ground data link or telephone.

height overlap coverage—A region of height-finder coverage within which there is duplicated coverage from adjacent height finders of other radar stations.

height-position indicator—A radar display that simultaneously shows the angular-elevation slant range and height of objects.

height-range indicator—A cathode-ray tube from which altitude and range measurements of airborne objects may be viewed.

Heising modulation—*See* constant-current modulation.

helical—Spiral-shaped.

helical antenna—Also called a helical-beam antenna. 1. A spiral conductor wound around a circular or polygonal cross section. The axis of the spiral normally is mounted parallel to the ground and fed at the adjacent end. The radiation produced has approximately a circular polarization and is confined mainly to a single lobe located along the axis of the spiral. 2. An antenna made of wire wound as a coil, usually on a Fiberglas rod and with the wire usually within Fiberglas.

Helical antenna.

helical-beam antenna—*See* helical antenna.

helical potentiometer—A precision potentiometer that requires several turns of the control knob to move the contact arm from one end of the spiral-wound resistance element to the other end.

helical scanning—1. Radar scanning in which the rf beam describes a distorted spiral motion. The antenna rotates about the vertical axis while the elevation angle rises slowly from 0° to 90° . 2. Method of facsimile scanning in which the elemental area sweeps across the copy in a spiral motion.

helical stripe—A continuous, colored, spiral stripe applied to a conductor for circuit identification.

helicone—A circularly polarized antenna that produces a low side-lobe level. It consists of a helix excited in the axial mode and placed inside a conical horn. The axial length of the helix is approximately equal to the altitude of the truncated cone.

helionics—The conversion of solar heat to electric energy.

helitron oscillator—An electrostatically focused, low-noise, backward-wave microwave oscillator. The frequency of the output signal can be swept rapidly through a wide range by variation of the voltage applied between the cathode and the associated rf circuit.

helium tight—*See* hermetic.

helix—A spiral winding, such as a coil.

helix recorder—A recorder in which helical scanning is used.

Helmholtz coil—A phase-shifting network used for determining the range in certain types of radar equipment. It consists of fixed and movable coils. The phase is kept constant at the input, but may be continually shifted from 0° to 360° at the output.

Helmholtz resonator—An acoustic enclosure with a small opening that causes the enclosure to resonate. The frequency at which it does depends on the geometry of the resonator.

hemimorphic—Terminated at the two ends by dissimilar sets of faces.

HEM wave—*See* hybrid electromagnetic wave.

henry—The cgs electromagnetic unit of inductance or mutual inductance. The inductance of a closed circuit in which an electromotive force of 1 volt is produced when the electric current in the circuit is varied uniformly at a rate of 1 ampere per second. Letter symbol: H.

heptode—A vacuum tube that contains seven electrodes: an anode, a cathode, a control electrode, and four additional electrodes, usually grids.

hermaphrodite connector—A cable connector in which the jack and the plug are identically shaped.

hermaphroditic connector—1. A connector in which both mating members are exactly alike at their mating face. There are no male or female members, but provisions have been made to maintain correct polarity, hot lead protection, sealing, and coupling. 2. Either of a pair of coaxial connectors whose mating faces are alike. 3. A connector design in which pin and socket contacts are arranged in a balanced manner such that both mating connectors are identical. The contacts may also be hermaphroditic and arranged as male and female contacts, as for pins and sockets. Hermaphroditic contacts may also be used in a manner such that one half of each contact mating surface protrudes beyond the connector interface, and both mating connectors are identical.

hermaphroditic contact—1. A contact designed so that it is neither pin nor socket and can be mated with any other contact of the same design. 2. Slotted contacts with beveled contacting surfaces in which both mating portions are exactly alike in shape, but mate at a 90° angle from each other.

hermetic—Also called helium tight, leak tight, and vacuum tight. 1. Pertaining to permanent sealing, by fusion, soldering, or other means, to prevent the transmission of gases. 2. A characteristic of packages providing an absolute seal against moisture to prevent degradation. These packages are generally metal cans, dual-in-line packages (DIPs) with solder seals, or ceramic packages. Plastic packages, although less expensive, are not hermetic.

hermetically sealed—Contained within an enclosure that is sealed by fusion or other comparable means to ensure a low rate of gas leakage over a long period. This generally refers to metal-to-metal or metal-to-glass seal.

hermetic seal—1. An airtight seal between two parts of a container, such as between the can and header of a metal component package. 2. A mechanical or physical closure that is impervious to moisture or gas, including air. Usually pertains to an envelope or enclosure containing electronic components or parts, or to a header. 3. An IC package enclosure technique by which the IC chip is completely protected from environmental contaminants.

herringbone pattern—Television interference seen as one or more horizontal bands of closely spaced V- or S-shaped lines.

hertz—The standard unit for frequency, equivalent to one cycle per second. Letter symbol: Hz. Named after H. R. Hertz, a 19th-century German physicist.

Hertz antenna—1. An antenna system that does not depend for its operation on the presence of ground. Its resonant frequency is determined by its distributed capacitance, which varies according to its physical length. 2. An elementary linear dipole radiator; it may or may not have spherical or flat-plate ends.

Hertz effect—The ionization and spark emission due to exposure to ultraviolet radiation.

Hertzian oscillator—A type of oscillator for producing ultrahigh-frequency oscillations. It consists of two metal plates or other conductors separated by an air gap. The capacitor formed has such a small capacitance that ultrahigh-frequency oscillations can occur.

Hertzian waves—Electromagnetic waves of frequencies between 10 kHz and 30,000 GHz. Radio waves.

hertz-matching loran—*See* low-frequency loran.

Hertz vector—A vector that specifies the electromagnetic field of a radio wave. Both the electric and the magnetic intensities can be specified in terms of it.

heterodyne—Also called beat. To mix two frequencies together in a nonlinear component in order to produce two other frequencies equal to the sum and difference of the first two. For example, heterodyning a 100-kHz and a 10-kHz signal will produce a 110-kHz (sum frequency) and a 90-kHz (difference frequency) signal.

heterodyne conversion transducer (converter)—A conversion transducer in which the output frequency is the sum or difference of the input frequency and an integral multiple of the frequency of another wave.

heterodyne detection—Detection (or conversion) by mixing two signals together to generate the intermediate frequency in a superheterodyne receiver or to make cw signals audible.

heterodyne detector—A detector that converts an incoming rf signal to an audible tone by heterodyning. It incorporates a local oscillator (called a beat-frequency oscillator).

heterodyne frequency—1. The sum or difference frequency produced by combining two other frequencies. 2. Either of the two frequencies, the sum or the difference, that result from an amplitude-modulation process.

heterodyne frequency meter—*See* heterodyne wavemeter.

heterodyne oscillator—An oscillator that produces a desired frequency by combining two other frequencies (e.g., two radio frequencies to produce an audio frequency, or the incoming and local-oscillator frequencies to produce the intermediate frequency of a superheterodyne receiver).

heterodyne principle—*See* heterodyne.

heterodyne reception—Also called beat reception. 1. Reception by combining a received high-frequency wave with a locally generated wave in a nonlinear device to produce sum and difference frequencies at the output. 2. A form of reception in which the receiver combines the incoming signal with a locally generated signal of different frequency. The combination creates a new signal, the intermediate frequency, at the difference, or beat, frequency between the two components.

heterodyne repeater—A radio repeater in which the incoming radio signals are converted to an intermediate frequency, amplified, and reconverted to another frequency band before being transmitted over the next repeater section.

heterodyne-type frequency meter—An instrument for measuring frequency by producing a zero

difference frequency (zero beat) between the signal under test and an internally generated signal.

heterodyne wavemeter—A wavemeter employing the heterodyne principle to compare the frequency being measured with a frequency being generated in a calibrated oscillator circuit.

heterodyne whistle—A steady squeal heard in a radio receiver when the signals from stations having nearly equal frequencies beat together.

heterodyning—*See* heterodyne.

heterogeneity—A state or condition of being unlike in nature, kind, or degree.

heterogeneous—Composed of different materials (opposite of homogeneous).

heterojunction—An interface between two semiconductors of different chemical compositions (for example, between indium gallium arsenide phosphide and indium phosphide) but not necessarily different majority carrier types (n-type or p-type).

heterosphere—The portion of the upper atmosphere in which the relative proportions of oxygen, nitrogen, and other gases are unfixed and radiation particles and micrometeoroids are mixed with the air particles.

heuristic—1. Pertaining to exploratory problem-solving methods in which solutions are discovered through evaluation of the progress made toward the final result (as opposed to algorithmic methods). 2. Empirical. Referring to knowledge or procedures determined by experience, but difficult to prove. 3. A problem-solving technique in which general principles and rules of thumb are used to approach a solution. Unlike an algorithm, the heuristic approach does not guarantee a solution. However, heuristic methods can result in a faster and simpler solution, and where algorithms are not available they are often the only resource. 4. A rule of thumb or an educated guess that simplifies and limits a search for solutions and applications that are difficult or poorly understood.

heuristic program—A set of computer instructions that simulate the behavior of human operators in approaching similar problems.

Hewlett-Packard Interface Bus—Abbreviated HP-IB. The Hewlett-Packard implementation of the IEEE-488 bus used to interface multiple devices by a well-defined hardware protocol. *See* GPIB.

hex—The hexadecimal numbering system. Since 16 is a power of 2, binary numbers are easily converted into hex, so machine-language computer programs are often written in hex to save space. For example, binary 11010110 (decimal 214) could be written in hex as D6.

hexadecimal—1. Number system using 0, 1, . . . , A, B, C, D, E, F to represent all the possible values of a four-bit digit. The decimal equivalent is 0 to 15. Two hexadecimal digits can be used to specify a byte. 2. A counting system similar to BCD. 3. A number system using the equivalent of the decimal number 16 as base. *Compare* binary number system.

hexadecimal counter—*See* divide-by-16 counter.

hexadecimal display—A solid-state display capable of exhibiting numbers 0 through 9 and alphabet characters A through F.

hexadecimal number system—A number system having as its base the equivalent of the decimal number 16.

hex inverter—A group of six logic inverters contained in a single package.

hexode—A vacuum tube containing six electrodes: an anode, a cathode, a control electrode, and three additional electrodes, usually grids.

HF—Abbreviation for high frequency.

Hexadecimal system

Decimal	Binary	Octal	Hexadecimal
0	0	0	0
1	1	1	1
2	10	2	2
3	11	3	3
4	100	4	4
5	101	5	5
6	110	6	6
7	111	7	7
8	1000	10	8
9	1001	11	9
10	1010	12	A
11	1011	13	B
12	1100	14	C
13	1101	15	D
14	1110	16	E
15	1111	17	F

H-field sensor—A passive sensor that detects changes in the earth's ambient magnetic field caused by the movement of an intruder. *See also* E-field sensor.

HH beacon—A nondirectional radio homing beacon with a power output of 2000 watts or more.

HIC—Abbreviation for hybrid integrated circuit.

hidden codes—Formatting codes embedded into a document that are not visible on the screen.

hidden file—Also called invisible file. A file in a computer that occupies disk space but does not appear in directory listings. Files are hidden to prevent their display or change. Users cannot display, erase, or copy hidden files.

hierarchical network—Also called a tree network. A network topology organized in the form of a pyramid with one terminal at the top and increasing numbers of terminals at each lower level.

hierarchy—1. A series of items classified according to rank or order. 2. The order in which arithmetic operations within a formula or a statement will be executed. 3. An arrangement into a graded series.

hi-fi—*See* high fidelity.

high-altitude electromagnetic pulse—An electromagnetic radiation of very short rise time, large amplitude, and brief duration that follows a nuclear explosion above the atmosphere.

high band—Television channels 7 to 13, covering a frequency range of 174 to 216 MHz.

high boost—*See* high-frequency compensation.

high-contrast image—A picture in which strong contrast between light and dark areas is visible. Intermediate values, however, may be missing.

high definition—The condition of a reproduced television or facsimile image in which it contains sufficient accurately reproduced elements for the picture details to approximate those of the original scene.

high-definition television—Abbreviated HDTV. A television picture of higher quality than standard NTSC video. This usually involves 720 lines, progressive scan more horizontal lines (e.g., 1080 or higher rather than 525), a different aspect ratio (16:9 rather than 4:3), and Dolby digital audio.

high-density disk—A floppy disk that holds more information than a double-density disk. A 3.5-inch high-density disk holds 1.44 megabytes.

high-energy materials—Also called hard magnetic materials. Magnetic materials having a comparatively high-energy product; e.g., materials used for permanent magnets.

higher-level language—A programming language that closely resembles natural language. A statement in a higher-level language will produce many machine-language instructions. The higher-level languages are usually independent of the computer.

highest probable frequency—Abbreviated HPF. An arbitrarily chosen frequency value 15 percent above the F_2 layer MUF (maximum usable frequency) for the radio circuit. For the E-layer, the HPF is equal to the MUF.

high fidelity—Popularly called hi-fi. 1. The characteristic that enables a system to reproduce sound as nearly like the original as possible. 2. Reproduction of audio so perfect that listeners hear exactly what they would have heard if present at the original performance. 3. The reproduction of audio sounds so perfectly that a listener is not aware of any loss of naturalness.

high-fidelity receiver—A radio receiver capable of receiving and reproducing, without noticeable distortion, the original modulation impressed on the carrier waves.

high filter—An audio circuit designed to remove undesired high-frequency noise from the program material. Such noise includes record scratch, tape hiss, AM whistles, etc.

high frequency—Abbreviated HF. The frequency bands from 3 to 30 MHz (100 meters to 10 meters).

high-frequency alternator—An alternator capable of generating radio-frequency carrier waves.

high-frequency band—The band of frequencies extending from 3 to 30 MHz.

high-frequency bias—In a tape recorder, a sinusoidal voltage that is mixed with the signal being recorded to improve the linearity and dynamic range of the recorded signal. In practice, the bias frequency is three to four times the highest information frequency to be recorded.

high-frequency carrier telegraphy—Carrier telegraphy with the carrier currents above the frequencies transmitted over a voice telephone channel.

high-frequency compensation—Also called high boost. An increase in the amplification of the high frequencies with respect to the low and middle frequencies within a given band of frequencies.

high-frequency heating—*See* electronic heating.

high-frequency induction heater or furnace—An induction heater or furnace using frequencies much higher than the standard 60 hertz.

high-frequency resistance—Also called rf or ac resistance. The total resistance offered by a device in a high-frequency ac circuit. This includes the dc and all other resistances due to the effects of the alternating current.

high-frequency treatment—Therapeutic use of intermittent and isolated trains of heavily damped oscillations having a high frequency and voltage and a relatively low current.

high-frequency trimmer—A trimmer capacitor that is used to calibrate the high-frequency end of the tuning range in a superheterodyne receiver.

high-frequency unit—*See* tweeter.

high-frequency welding—*See* radio-frequency welding.

high-intensity discharge lamps—Abbreviated HID. A general group of lamps, consisting of mercury, metal halide, and high-pressure sodium lamps.

high-K ceramic—A ceramic dielectric composition (usually BaTiO₃) that exhibits large dielectric constants

and nonlinear voltage and temperature response characteristics.

high level—1. In digital logic, the more positive of the two binary-system logic levels. 2. Commands for computer systems in which each instruction is actually equated to many machine-code instructions strung together. *See also* low level; negative logic; positive logic. 3. Term describing a computer language in which the statements are closer to human communication than to machine code. Usually high-level languages can be easily read and understood by people since they consist of pseudo-English statements. To be used by a processor, high-level statements must be translated into machine code.

high-level crossover network—A crossover network designed to operate at high levels and which is placed between the power amplifier and the speakers (this type of crossover is normally built into a speaker system).

high-level data link control—*See* HDLC.

high-level detector—A linear power detector with a voltage-current characteristic that may be treated as a straight line or two intersecting lines.

high-level firing time—The time required to establish a radio-frequency discharge in a switching tube after radio-frequency power is applied.

high-level language—1. An application or problem-oriented programming language, as distinguished from a machine-oriented programming language. The instruction approach is closer to the needs of the problems to be solved than it is to the language of the machine on which it is to be run. Examples are Ada, C, COBOL, FORTRAN, Lisp, and Pascal. 2. Any programming language that allows a person to give instructions to a computer in English-like text rather than in the numerical (binary) code of 1s and 0s that the computer understands. FORTRAN and BASIC are high-level languages. 3. A step above assembly language. It can be translated to a lower level but not into English except by a programmer. 4. A sophisticated, though easy to use, computer language (written words and special punctuation) that allows a programmer to write software without being concerned with housekeeping functions (e.g., register allocation) or optimization.

high-level modulation—A system in which the modulation is introduced at a point where the power level approximates the output power.

high-level radio-frequency signal (tr, atr, and pre-tr tubes)—A radio-frequency signal with sufficient power to fire the tube.

high-level VSWR (switching tubes)—The voltage standing-wave ratio caused by a fired tube located between a generator and the matched termination in a waveguide.

highlight—The brightest portion of a reproduced image.

high-mu tube—A vacuum tube with a high amplification factor.

high-noise-immunity logic—Abbreviated HNIL. A special type of logic designed specifically to provide very high resistance to electrical noise. Sometimes called HTL (high-threshold logic).

high-order language—A programming language that is independent of the computer. Usually, it resembles natural languages, and a compiler is required for translation into machine language. Examples are FORTRAN and ALGOL.

high-pass filter—1. A wave filter having a single transmission band extending from some critical, or cutoff, frequency other than zero, up to infinite frequency. 2. A filter that, above a critical frequency, allows the unrestricted passage of high-frequency signals.

High-pass RC filter.

Reciprocally, a bass-cut filter. 3. A filter that passes frequency components above some limited frequency and rejects components below that limit.

high-performance equipment—Equipment having sufficiently exacting characteristics to permit their use in trunk or link circuits.

high pot—*See* flash test.

high-potential test—A test for determining the breakdown point of insulating materials and spacings. It consists of applying a voltage higher than the rated voltage between two points or between two or more windings. However, it is not a test of conductor insulation.

high potting—*See* flash test.

high-power silicon rectifiers—A group of rectifiers with continuous ratings exceeding 50 average amperes per section in a single-phase, half-wave circuit.

high Q—Having a high ratio of reactance to effective resistance. The factor determining the efficiency of a reactive component.

high-rate discharge—The storage-battery discharge equivalent to the heaviest possible duty in service.

high-recombination rate contact—A semiconductor contact at which thermal equilibrium charge-carrier concentrations are maintained substantially independent of current density.

high-resistance joint—A faulty union of conductors and conductor and terminal. The result is less current flow and a drop in voltage at the union.

high-resistance voltmeter—A voltmeter having a resistance considerably higher than 1000 ohms per volt. As a result, it draws very little current from the circuit being measured.

high resolution—Descriptive of a camera or monitor capable of displaying a great number of scanning lines (1000–2000), which produces a picture that is very detailed, defined, and sharp.

high-speed bus—*See* memory register.

high-speed carry—Also called standing-on-nines carry. 1. A carry into a column results in a carry out of that column, because the sum without carry in that column is 9. 2. Instead of a normal adding process, a special process is used which takes the carry at high speed to the actual column where it is added.

high-speed data rate—Data transmission at a rate between 2401 bauds and 500 kilobauds.

high-speed dc circuit breaker—A device that starts to reduce the current in the main circuit in 0.01 second or less after the occurrence of a dc overcurrent or an excessive rate of current rise.

high-speed excitation system—An excitation system that can change its voltage rapidly in response to a change in the field circuit of the excited generator.

high-speed pattern board—Board completely covered with copper foil on both sides with the exception of small annular rings etched away to provide isolated interconnections. High V_{CC} and ground-plane coverage

high-performance equipment — hinge

enhance high-speed logic operation due to afforded control of signal-line impedance and reduction of noise and crosstalk.

high-speed printer—1. A printer that has a speed of operation compatible with the speed of computation and data processing so that it may operate online. 2. A signal-responsive alphanumeric printer capable of printing computer output signals at rates on the order of 300 characters per second or greater.

high-speed reader—A reading device that can be connected to a computer so as to operate online without seriously slowing the operation of the computer.

high-speed relay—A relay designed specifically for short operate or short release time, or both.

high-speed storage—*See* rapid storage.

high-speed telegraph transmission—Transmission of code at higher speeds than are possible with hand-operated keys.

high state—The relatively more positive signal level used to assert a specific message content associated with one of two binary logic states.

high-tech—A general term that refers to sophisticated technical innovation; cutting-edge technology, often involving computers and other electronic devices.

high-temperature reverse bias—Burning-type test of diodes and transistors, conducted with the junctions reverse biased to effect any failure due to ion migration in bonds of dissimilar metals.

high-tension—Lethal voltages, on the order of thousands of volts.

high-tension magneto—A self-contained generator in which the required high potential is generated directly; no induction coil is needed.

high-threshold logic—Abbreviated HTL. 1. Logic with a high noise margin, used primarily in industrial applications. It closely resembles diode-transistor logic (DTL), except that in HTL a reverse-biased emitter junction is used as a threshold element operating as a zener diode. A typical noise margin is 6 volts with a 15-volt supply. 2. Logic that allows for higher degree of inherent electrical noise immunity. A considerably larger input threshold characteristic is exhibited by HTL devices by using a reversed-biased base-emitter junction that operates in the breakdown avalanche mode. A higher input signal is required to turn on the HTL output-inverting transistor than the DTL.

high-vacuum phototube—A phototube that is highly evacuated so that its electrical characteristics are essentially unaffected by gaseous ionization. In a gas phototube, some gas is intentionally introduced.

high-vacuum rectifier—A vacuum-tube rectifier in which conduction is entirely by electrons emitted from the cathode.

high-vacuum tube—Also known as a hard tube. An electron tube whose electrical characteristics will not be affected by gaseous ionization because of its high degree of evacuation.

high-velocity scanning—The scanning of a target with electrons of such velocity that the secondary-emission ratio is greater than unity.

high voltage—The accelerating potential that speeds up the electrons in a beam of a cathode-ray tube.

high-voltage probe—A probe with a high internal resistance, for measuring extremely high voltages. It is used with a voltmeter having an internal resistance of 20,000 ohms per volt or more. *See* Figure on p. 352.

hill-and-dale recording—*See* vertical recording.

hinge—A joint in a relay that permits movement of the armature relative to the stationary parts of the relay structure.

High-voltage probe.

H-network.

hinged-iron ammeter — A moving-iron ammeter in which the fixed portion of the magnetic circuit is placed around the conductor to measure the current through it.

HIPERNAS — Acronym for *high-performance navigation system*. A self-compensated, pure-inertial guidance system.

hipot — 1. See dielectric breakdown voltage. 2. Contraction of high potential. Commonly refers to a device used, with high voltages, for testing insulation breakdown or leakage. High potting is the verb. 3. High-potential voltage applied across a conductor to test the insulation. 4. A test designed to determine the highest potential that can be applied to a conductor without breaking through the insulation.

hipot tester — A *high-potential* test instrument that applies a high-voltage source to the insulating material of a device or cable to determine the ability of the unit to withstand the voltage without breakdown.

hi-rel — A contraction of high reliability; refers to products that are assembled and inspected under rigid standards, given extra testing and conditioning, and typically used in military, space, or medical applications.

hiss — 1. Random noise characterized by prolonged sibilant sounds in the audio-frequency range. 2. The primary background noise in tape recording, stemming from circuit noise in the playback amplifiers or from residual magnetism of the tape.

histogram — 1. A graphical representation of a frequency distribution by a series of rectangles that have for one dimension a distance proportional to a definite range of frequencies, and for the other dimension a distance proportional to the number of frequencies appearing within range. 2. A description of one (or all) parameters, showing distribution, standard deviation, mean-value failure limits, and sample lot size for all samples within the lot. 3. A graph of contiguous vertical bars representing a frequency distribution in which the groups or classes of items are marked on the *x*-axis, and the number of items in each class is indicated by a horizontal line segment drawn above the *x*-axis at a height equal to the number of items in the class.

hit — 1. See flash. 2. Momentary surge of voltage on a transmission channel. 3. An impulse noise having a duration of about 1 millisecond.

hit-on-the-fly printer — 1. A mechanical printer in which the printing head is in continual motion. 2. A printer in which the paper and/or the printing mechanism are in constant motion so that starts and stops are not needed.

hits — Momentary line disturbances that could result in mutilation of characters being transmitted.

H-lines — Imaginary lines that represent the direction and strength of magnetic flux on a diagram.

HNDDT — See holographic nondestructive testing.

H-network — A network composed of five impedance branches. Two are connected in series between an input terminal and an output terminal, and two are connected between another input and another output terminal. The fifth is connected from the junction points of the two branches.

HNIL — Abbreviation for high-noise-immunity logic.

hobby computer — A computer that is not used for profit.

hog horn — A microwave feed horn shaped so that the input energy from the waveguide approaches from the same direction as the horn opening.

hold — Opposite of clear. 1. To maintain storage elements in charge storage tubes at equilibrium potentials by electron bombardment. 2. To retain the information contained in one storage location for a computer after copying the information into another storage location, as opposed to clearing or erasing the information. 3. To maintain an established telephone connection, possibly while disconnecting to answer another call.

hold control — In a television receiver, the adjustment that controls the frequency of the vertical or horizontal scanning pulses and hence the stability of the picture.

hold current — Also called the electrical hold value. The minimum current that will keep the contact springs energized in a relay.

hold electrode — In a mercury switch, the electrode that remains in contact with the mercury pool while the circuit is being closed or opened.

holding anode — In a mercury-arc rectifier, a small auxiliary anode that maintains the ionization while the main anode current is zero.

holding beam — A diffused beam of electrons for regenerating the charges retained on the dielectric surface of an electrostatic memory or storage tube.

holding circuit — Also called a locking circuit. An alternate operating circuit that, when completed, maintains sufficient current in a relay winding to keep the relay energized after the initial current has ceased.

holding coil — A separate relay coil that keeps the relay energized after the original current has been removed.

holding current — 1. That value of average forward current (with the gate open) below which a silicon-controlled rectifier returns to the forward blocking state after having been in forward conduction. 2. The minimum current that must pass through a device such as a silicon-controlled rectifier, thyatron, neon glow tube, etc., to maintain it in a conducting condition. 3. The minimum current that will hold a relay in its operated position. The holding current is less than the operating current. 4. The minimum principal current required to maintain a thyristor in the on state.

holding gun — In a storage tube, the source of electrons constituting the holding beam.

holding time — The total time a trunk or circuit is in use on a call, including both operator's and user's time.

holding torque — Also called restoring or stall torque. 1. Force moment required to deflect the rotor of a stepper motor a full step with the motor energized but at a standstill. 2. A measure of the maximum torque that can be applied to the shaft of a stepper motor with one or more of its phases energized before the shaft begins to rotate.

hold lamp — An indicating lamp that stays lighted while a telephone connection is being held.

hold mode — In integrators or other charge-storage circuits, a condition or time interval in which input(s) are removed and the circuit is commanded (or expected) to maintain a constant output.

hold-mode drop — In a sample-and-hold circuit, the output voltage change per unit of time while in hold. Commonly specified in volts per second, microvolts per microsecond, and other convenient units.

hold-mode feedthrough — In a sample-and-hold circuit, the percentage of an input sinusoidal signal that is measured at the output of a sample hold when it is in hold mode.

hold-mode settling time — In a sample-and-hold circuit, the time from the hold-command transition until the output of the sample hold has settled within the specified error band. It includes aperture delay time.

hold-off voltage — The maximum voltage an electronic flash tube will stand without self-flashing. Normal hold-off voltage is reduced at the end of lamp life and in the presence of high temperatures or rf fields.

holdover — The condition that occurs when a lighting-protector gap continues to conduct follow current.

holdover time — Also called holdup time. The length of time a power supply will maintain its rated output after the input has been lost. In nonuninterruptible power supplies, the holdover time is usually measured in milliseconds.

holdover voltage — The steady-state voltage at which a gap just fails to clear a given value of follow current.

hold time — Also called release time. 1. In resistance welding, the time that is allowed for the weld to harden. 2. The length of time after the clocking of a flip-flop that data must remain unchanged.

holdup — The ability of a power supply to provide energy for approximately 30 to 50 milliseconds after an ac power loss. This provides an adequate amount of time to make a transfer to a standby power system. Holdup time is especially useful in computer systems, in which data in volatile memories may be lost in nuisance shutdowns.

holdup button — A manually actuated mechanical switch used to initiate a duress alarm signal; usually constructed to minimize accidental activation.

holdup time — See holdover time.

hole — 1. In the electronic valence structure of a semiconductor, a mobile vacancy that acts like a positive electronic charge with a positive mass. 2. In a semiconductor, the term used to describe the absence of an electron; this absence has the same electrical properties as an electron except that it carries a positive charge. 3. A mobile vacancy or electron deficiency in the valence structure of a semiconductor. It is equivalent to a positive charge. 4. A defect in the valence electron system of a semiconductor crystal lattice, equivalent to the absence of a single valence electron. Like a conduction electron, a hole is capable of moving through the crystal and thus forms an effective current carrier having a positive charge. However, unlike a conduction electron, the hole must remain in the valence-bonding system of the crystal and thus it has a lower mobility.

hole conduction — Conduction occurring in a semiconductor when electrons move into holes under the influence of an applied voltage and thereby create new holes. The apparent movement of such holes is toward the more negative terminal, and is hence equivalent to a flow of positive charges in that direction.

hole current — Conduction in a semiconductor when electrons move into holes, creating new holes. The holes appear to move toward the negative terminal, giving the equivalent of positive charges flowing to the terminal.

hole density — In a semiconductor, the density of holes in an otherwise full band.

hole-electron pair — A positive charge carrier (hole) and a negative charge carrier (electron) considered together as one entity.

hole injection — The production of mobile vacancies in an n-type semiconductor when a voltage is applied to a sharp metal point in contact with the surface of the material.

hole injector — A pointed metallic device for injecting holes into an n-type semiconductor.

hole-in-the-center effect — Also called hole-in-the-middle effect. The lower volume or absence of sound between the left and right speakers of a stereo system.

hole mobility — The ability of a hole to travel easily through a semiconductor.

hole site — The area on a computer punch card or paper tape where a hole may or may not be punched. It can be a form of binary storage, in which a hole represents a 1 and the absence of a hole represents a 0.

hole storage factor — In a transistor, the excess stored charge (when the transistor is in saturation) per unit excess base current. Excess base current is defined as the amount of current supplied to the base in excess of the current required to just keep the transistor in saturation.

hole trap — A semiconductor impurity that can trap holes by releasing electrons into the conduction or valence bands.

Hollerith — Pertaining to a particular type of code or punched card utilizing 12 rows per column and usually 80 columns per card.

Hollerith code — 1. A code based on the punching of holes in cards at specified locations. From one to three punches may be made in each column of the card and up to 80 columns may be punched in each card. Each column corresponds to one character; the specific character is determined by the number and location of the punches in that column. 2. A 12-level (12 bits per character) code that defines the relation between an alphanumeric character and the punched holes in an 80-column data card.

hollow-cathode tube — A gas discharge tube with a hollow cathode closed at one end. Almost all the radiation is from the cathode glow within the hollow cathode.

hollow core — A plain ferrite core having a center hole for mounting purposes.

hologram — 1. A photograph, made with laser light, that appears to have three dimensions. 2. A recording of the two-dimensional intensity distribution of the interference pattern produced by the interaction of two or more monochromatic waves that have phases derived from the same source. One of the waves is reconstructed when a replica of the other wave is diffracted from the hologram. 3. An interference pattern recorded on photographic film or similar media. This pattern is created by directing two beams of coherent light into the film. One, called the reference beam, strikes the film directly. The second, called the object beam, bounces off, or passes through the test specimen, then strikes the film. The interaction of these two beams makes up the interference pattern called a hologram. To "decode" the swirls and dots of the pattern and create a visible

three-dimensional image, a coherent light beam is directed onto the hologram.

holographic cinematography — A technique used to create a succession of interrelated holographic images that give an appearance of motion when projected in sequence. A flashing laser is used in both the recording and projecting of the images.

holographic display — A three-dimensional display created by using lasers.

holographic lenses — Photographic recordings of interference patterns between a plane wave and a spherical wave on a high-resolution photographic emulsion.

holographic memory — The storage of data as bits in memory by holographic processes. A laser beam is divided into reference and object beams, and bit information is stored as a hologram.

holographic nondestructive testing — Abbreviated HNDT. The application of coherent wavefront techniques to the determination of the physical state of a system without appreciably altering that state.

holography — 1. The optical recording of an object wave formed by the resulting interference pattern of two mutually coherent component light beams. A coherent beam is first split into two component beams, one of which irradiates the object, the second of which irradiates a recording medium. The diffraction or scattering of the first wave by the object forms the object wave that proceeds to and interferes with the second coherent beam, or reference wave, at the medium. The resulting pattern is a three-dimensional record (hologram) of the object wave. 2. The recording of an object wave (usually optical) in such a way that an identical wave can subsequently be reconstructed. Whereas a conventional photograph records only the intensity of the light incident on it, a hologram records both the amplitude and phase. The additional phase information is contained in an interference pattern that is formed from the object wave and a reference wave. 3. The science and technique of producing holograms.

holtite contact system — A pluggable solderless means of connecting DIP, SIP, and discrete-component packages to printed circuit boards with none of the socket material showing above the board surface.

Home Box Office — See HBO.

home loop — An operation involving only those input and output units associated with the hole terminal.

home-on-jam — A radar feature that permits angular tracking of a jamming source.

home page — 1. An HTML document associated with an individual or organization. It contains text, pictures, sounds, and links to other sites that appear (generally in blue) as underlined words or phrases. Clicking on these underlined words opens a network connection to other HTML documents, which can be anywhere on the Internet, or spawns an application on the host computer. 2. An HTML page that is the primary or index document representing an entity such as a company or individual. It is usually the first page received from a web server and, as such, serves as an introduction to the entity or content being served. 3. The first screen of a collection of web sites particular to one person or business.

homotaxial-base transistor — A transistor manufactured by a single-diffusion process so that both the emitter and collector junctions are formed in a uniformly doped silicon slice. The homogeneously doped base region that results is free from accelerating fields in the axial (collector-to-emitter) direction; such fields could cause undesirable high flow and destroy the transistor.

homing — 1. Approaching a desired point by maintaining some indicated navigational parameter constant

(other than altitude). 2. In missile guidance, the use of radiation from a target to establish a collision course.

homing adapter — A device used with an aircraft radio receiver to produce aural and/or visual signals that indicate the direction of a transmitting radio station.

homing antenna — A type of directional-antenna array used for pinpointing a target.

homing beacon — A radio transmitter that emits a distinctive signal for determining bearing, course, or location.

homing device — 1. An automatic device that moves or rotates in the correct direction without first having to go to the end of its travel in the opposite direction. 2. A radio device that guides an aircraft to an airport or transmitter site.

homing guidance — A missile-guidance system in which the missile steers itself toward a target by means of a self-contained mechanism (infrared detectors, radar, etc.). It is activated by some distinguishing characteristic of the target. Homing guidance may be active, semi-active, or passive.

homing guidance system — A system of sensors and related instrumentation that allows a navigable object (usually a missile) to locate its destination by some distinguishing characteristics of that target, and then calculate and alter its course so that the destination is reached.

homing relay — A stepping relay that returns to a specified starting position prior to each operating cycle.

homing station — A radionavigational aid incorporating direction-finding facilities.

homodyne reception — Also called zero-beat reception. 1. A form of reception in which the receiver generates a signal at the original carrier frequency and combines it with the incoming signal. 2. A system of reception using a locally generated voltage at the carrier frequency.

homogeneity — The state or condition of being similar in nature, kind, or degree.

homogeneous — Of the same nature (the opposite of heterogeneous). That property of a substance that determines that all components of volume are the same relative to composition and other properties.

homogeneous crystal — Crystalline material having a uniform composition. In the context of impurity semiconductor materials, a homogeneous crystal is one having a uniform doping concentration.

homogeneous multiprocessor — A multiprocessor in which all processors of significance are functionally identical.

homologous field — A field in which the lines of force in a given plane all pass through one point (e.g., the electric field between two coaxial charged cylinders).

homopolar — Electrically symmetrical, i.e., having equally distributed charges.

homopolar generator — A dc generator in which all the poles presented to the armature are of the same polarity, so that the armature conductor always cuts the magnetic lines of force in the same direction. A pure direct current can thus be produced without commutation.

homopolar magnet — A magnet with concentric pole pieces.

homosphere — That part of the atmosphere which is made up mostly of atoms and molecules found near the earth's surface and which retains the same relative proportions of oxygen, nitrogen, and other gases throughout.

homotaxial — A term coined by RCA from *homogeneous* and *axial* to describe a single-diffused transistor with a base region of homogeneous resistivity silicon on the axial (emitter-to-collector) direction.

honeycomb coil—An air-core radio-frequency inductance wound in a crisscross lattice to reduce its distributed capacitance.

honeycomb winding—A method of winding a coil with crisscross turns to minimize distributed capacitance.

hood—1. A shield placed over a cathode-ray tube to eliminate extraneous light and thus make the image on the screen appear more clearly. 2. An enclosure, attached to the back of a connector, to contain and protect wires and cable attached to the terminals of a connector. A cable clamp is usually an integral part of the hood.

hood contact—A switch that is used for the supervision of a closed safe or vault door. Usually installed on the outside surface of the protected door.

hook—1. Hidden capacitance between conductors on a printed wiring board. Molecular structure causes capacitance change with frequency. Hook is responsible for signal-waveshape distortion and timing problems. 2. The effect on a signal's voltage caused by a change in printed circuit board capacitance with frequency. Board capacitance is created between printed circuit board conductors separated by dielectric material. It can change the response time of a square wave and can bring about erroneous responses at certain frequencies of sine waves.

hookswitch—The device on which a telephone receiver hangs or on which a telephone handset hangs or rests when not in use. The weight of the receiver or handset operates a switch that opens the telephone circuit, leaving only the bell connected to the line. When the handset is lifted, the switch closes the telephone circuit or loop.

hook terminal—Terminal with a hook-shaped tongue.

hook tongue—Type of terminal with a tongue that opens from the side rather than from the end.

hook transistor—A transistor having four alternating p-type and n-type layers, with one layer floating between the base layer and the collector layer. This arrangement gives high emitter-input current gains. The pnp transistor has a p-type floating layer, while the npn transistor has an n-type floating layer.

hookup—1. Method of connection between the various units in a circuit. 2. The diagram of connections used. 3. An interconnection of circuit components for a particular purpose.

hookup wire—1. The wire used in coupling circuits together. It may be solid or stranded, and is usually tinned and insulated No. 18 or 20 soft-drawn copper. 2. Wire used for point-to-point connection within electronic equipment, usually carrying low voltages (under 1000 V) and currents. 3. Wire used to make the internal connections between the various electrical parts of electronic assemblies.

hop—An excursion of a radio wave from the earth to the ionosphere and back. It is usually expressed as single-, double-, and multihop. The number of hops is called the order of reflection.

hopoff—In a potentiometer, the sudden jump in resistance as the contact is rotated over the junction of two resistance slopes. The magnitude of the hopoff is dependent on the ratio of the slopes and on the junction blending characteristic.

hopper—An area in a temporary memory unit, such as a call store, used to record a list of items for subsequent communications with processing programs or input-output programs sent to central control.

horizon—An apparent or visible junction of earth and sky as seen on or above the earth. It bounds the part of the earth's surface that can be reached by the direct wave

of a radio station. The distance to the horizon is affected by atmospheric refraction.

horizon distance—The space between the farthest visible point and the transmitter antenna. It is the distance over which ultrahigh-frequency transmission can be received under ordinary conditions with an unelevated receiving antenna.

horizontal—1. Perpendicular to the direction of gravity. 2. In the direction of or parallel to the horizon. 3. On a level.

horizontal angle of deviation—The horizontal angle between the great-circle path from the transmitter to the receiver and the direction of departure or arrival of the wave along the line of propagation.

horizontal axes—The three horizontal axes of crystallographic reference.

horizontal blanking—Cutting off the CRT electron beam between successive active horizontal lines during retrace. Blanking of the picture during the period of horizontal retrace.

horizontal blanking interval—The brief time between scan lines required for the scanning electron gun to retrace from the right edge of the image back to the left to begin the next scan line.

horizontal blanking pulse—A rectangular pedestal in the composite television signal. It occurs between active horizontal lines and cuts off the beam current of the picture tube during retrace.

Horizontal blanking pulse.

horizontal centering control—In a television receiver or cathode-ray oscilloscope, the adjustment for moving the entire display back and forth.

horizontal-convergence control—In a color television receiver, the control that adjusts the amplitude of the horizontal dynamic convergence voltage.

horizontal definition—See horizontal resolution.

horizontal-deflecting electrodes—A pair of electrodes that move the electron beam from side to side on the screen of a cathode-ray tube employing electrostatic deflection.

horizontal-discharge tube—A vacuum tube used in the horizontal-deflection circuit to discharge a capacitor and thereby form the sawtooth scanning wave. See also discharge tube.

horizontal-drive control—In an electromagnetically deflected television receiver, the control that adjusts the ratio of the pulse amplitude to the linear portion of the scanning-current wave.

horizontal dynamic convergence—Convergence of the three electron beams in a color picture tube at the aperture mask during scanning of a horizontal line.

horizontal field-strength diagram—A representation of the field strength in a horizontal plane and at

a constant distance from an antenna. Unless otherwise specified, the plane passes through the antenna.

horizontal frequency — *See* line frequency, 1.

horizontal hold control — A synchronization control that varies the free-running frequency of the horizontal deflection oscillator so it will be in step with the scanning frequency at the transmitter.

horizontal hum bars — Broad, horizontal, moving or stationary bars, alternately dark and light, that extend over an entire television picture. They are caused by interference at approximately 60 Hz or a harmonic of 60 Hz.

horizontal-linearity control — In a television receiver, the control for adjusting the width at the left side of the screen.

horizontal line frequency — *See* line frequency, 1.

horizontal lock — The circuit that maintains horizontal synchronization in a television receiver.

horizontally polarized wave — A linearly polarized wave with a horizontal electric-field vector.

Horizontally polarized wave.

horizontal-output transformer — *See* flyback transformer.

horizontal parabola control — *See* phase control, 1.

horizontal polarization — 1. Transmission in which the electrostatic field leaves the antenna in a horizontal plane. Elements of the transmitting and receiving antennas likewise are horizontal. Horizontal polarization is standard for television in the United States. 2. Transmission of radio waves whose undulations vary horizontally with respect to the earth. (Horizontally polarized antennas are used mainly for base-to-base transmission.)

horizontal redundancy checking — *See* HRC.

horizontal repetition rate — Also called horizontal scanning frequency. The number of horizontal lines per second (15,750 hertz in the United States).

horizontal resolution — Also called horizontal definition. 1. The number of individual picture elements that can be distinguished in a horizontal scanning line. 2. The capability of a TV system to resolve detail in a horizontal direction across the screen. The higher the resolution number, the sharper the picture will be. 3. The number of vertical lines that can be displayed in a picture width equal to the picture height. This measurement is usually done via direct (RGB or Y/C) input in order to bypass limiting factors such as transmission standards (bandwidth, color carrier, etc.). For standard NTSC (60 Hz, 525 lines, 4:3 aspect ratio) and PAL (50 Hz, 625 lines, 4:3 aspect ratio), the picture is in practice the same: 80 lines per MHz bandwidth.

horizontal retrace — 1. The return of the electron beam from the right to the left side of a CRT raster after the scanning of one line. 2. The line that would be seen on a CRT screen while the spot is returning from right to left, if retrace blanking were not used.

horizontal ring-induction furnace — A furnace for melting metal. It comprises an open trough or melting

channel, a primary inductor winding, and a magnetic core that links the melting channel to the primary winding.

horizontal-scanning frequency — *See* horizontal repetition rate.

horizontal sweep — Movement of the electron beam from left to right across the screen or the scene being televised.

horizontal-sync discriminator — A circuit employed in the flywheel method of synchronization to compare the phase of the horizontal-sync pulses with that of the horizontal-scanning oscillator.

horizontal-sync pulse — The rectangular pulse that occurs above the pedestal level between each active horizontal line. The pulses keep the horizontal scanning at the receiver in step with that at the transmitter.

horn — Also called an acoustic horn. 1. A tubular or rectangular enclosure for radiating or receiving acoustic waves. 2. A primary element consisting of a section of metal waveguide in which one or both of the cross-sectional dimensions increase toward the open end. 3. Any flared or funnel-shaped passage used to couple a speaker efficiently to the air in the environment. It also provides control over sound dispersion pattern over a specified frequency range. The driver is connected to the throat of the horn, and the sound emerges from its mouth. *See also* horn antenna.

horn antenna — Also called a horn. 1. A tubular or rectangular microwave antenna that is wider at the open end and through which radio waves are radiated into space. 2. A microwave antenna formed by flaring the end of a waveguide into the shape of a horn.

Horn antenna.

horn arrester — A lightning arrester that has a spark gap with upward-projecting diversion horns of thick wire. When the arc is formed, it travels up the gap and is extinguished upon reaching the widest part of the gap.

horn cutoff frequency — A frequency below which an exponential horn will not function correctly because it fails to provide for proper expansion of the sound waves.

horn gap — A type of spark gap with divergent electrodes.

horn-gap switch — A form of air switch with arcing horns.

horn loading — A method of coupling a speaker diaphragm to the listening space by an expanding air column having a small throat and large mouth.

horn loudspeaker — A very directional speaker in which the driver is fed into a metal horn, whose flare is usually an exponential curve.

horn mouth — An open-ended metallic device for concentrating energy from a waveguide and directing this energy into space.

horn speaker — A speaker in which a horn couples the radiating element to the medium.

horn throat — The narrow end of a horn.

horsepower—Abbreviated hp. A unit of power, or the capacity of a mechanism to do work. It is the equivalent of raising 33,000 pounds 1 foot in 1 minute, or 550 pounds 1 foot in 1 second. One horsepower equals 746 watts.

horseshoe magnet—A permanent magnet or electromagnet shaped like a horseshoe or U to bring the two poles close together.

Horseshoe magnet.

host—1. A node computer on a network. The etymology of the term *host* may be from the days when a computer on a network hosted multiple users and services. 2. Any computer on a network that is a repository for services available to other computers on the network. It is quite common to have one host machine provide several services, such as WWW and Usenet. 3. The primary or controlling computer in a multiple-part system.

host computer—1. In the context of networks, a computer that directly provides service to a user. In contrast to a network server, which provides services to a user through an intermediary host computer. 2. The master or controlling computer in a multicomputer network. 3. A computer that prepares programs to be run on another computer system. 4. A computer that monitors and controls other computers and programmable controllers. 5. The central computer (or one of a collection of computers) that provides functions such as computation, database access, or special programs or programming languages; often shortened to *host*. 6. The central computer (or one of a collection of computers) in a data-communications system, which provides the primary data-processing functions such as computation, database access, or special programs or programming languages.

host system—The computer system in which an emulation program or accessory card is used to imitate another system.

hot—1. Connected, alive, energized; pertains to a terminal or any ungrounded conductor. 2. Not grounded. 3. Strongly radioactive. 4. Excited to a relatively high energy level. 5. Idiomatic term generally used to describe conductors carrying an electrical charge.

hot-carrier diode—Abbreviated HCD. A diode in which a closely controlled metal-semiconductor junction provides virtual elimination of charge storage. The device has extremely fast turn-on and turn-off times, excellent diode forward and reverse characteristics, lower noise characteristics, and wider dynamic range. *See* Schottky barrier diode.

hot carriers—In barrier diodes, carriers that have energies greater than those that are in terminal equilibrium with the metal. Thus, electrons that cross the junction from semiconductor to metal must be energetic enough to surmount the barrier. Therefore, electrons that are energetic enough to cross the junction are called hot electrons.

hot cathode—Also called thermionic cathode. 1. A cathode that supplies electrons by thermionic emission. (As opposed to a cold cathode, which has no heater.) 2. An electron-tube cathode in which electron emission is produced by heat.

hot-cathode tube—Also called thermionic tube. Any electron tube containing a hot cathode.

hot-cathode X-ray tube—A high-vacuum X-ray tube in which a hot rather than cold cathode is used.

hot electrons—*See* hot carriers.

hot-electron triode—A solid-state, evaporated-thin-film structure that is directly equivalent to a triode vacuum tube.

hotkey—A single key or a simple key combination that can be used to activate a computer program, or a function in a program.

hot line—Communications channel between two points available for immediate use without patching or switching.

hot plate—Electrically heated flat surface, sometimes combined with auxiliary equipment such as a magnetic stirrer.

hot spot—The point of maximum temperature on the outside of a device or component.

hot-spot temperature—The maximum temperature measured on a resistor due to both internal heating and the ambient operating temperature. Maximum hot-spot temperature is predicted on thermal limits of the materials and the design. The hot-spot temperature is also usually established as the top temperature on the derating curve at which the resistor is derated to zero power.

hot stamping—Method of imprinting letters, numbers, and symbols with a heated die.

hot tin dip—A process of passing a bare wire through a bath of molten tin to provide a coating.

hot-wire ammeter—Also called thermal ammeter. An ammeter in which the expansion of a wire moves a pointer to indicate the amount of current being measured. The current flows through the wire and changes its length in proportion to I^2 . Instability because of wire stretching, and the lack of ambient temperature compensation, make the hot-wire ammeter commercially unsatisfactory.

Hot-wire ammeter.

hot-wire anemometer—An instrument that measures the velocity of wind or a gas by its cooling on an electrically heated wire.

hot-wire instrument—1. An electrothermic instrument operated by expansion of a wire heated by the current it is carrying. 2. A measuring device or transducer whose operation depends either on the expansion of a wire due to its being heated by an electric current or on the change in electrical resistance on the part of a wire that is heated or cooled.

hot-wire microphone—A microphone in which the cooling or heating effect of a sound wave changes the resistance of a hot wire and thus the current through it.

hot-wire relay—A form of linear-expansion time-delay relay in which the longitudinal expansion of a wire, when heated, provides the mechanical motion to open or close contacts. The time required to heat the wire constitutes the delay.

hot wires—In an electrical system, those wires that carry the live current through the electrical system. Hot wires are usually black or red.

hot-wire transducer—A unilateral transducer in which the cooling or heating effect of a sound wave changes the resistance of a hot wire and thus the current.

house cables—Conductors inside a building used to connect communication equipment to outside lines.

housekeeping—In a computer routine, those operations, such as setting up constants and variables for use in the program, that contribute directly to the proper operation of the computer but not to the solution of the problem.

howl—An undesirable prolonged wail produced in a speaker by electric or acoustic feedback.

howler—1. An electromechanical device that produces an audio-frequency tone. 2. A unit by which the operator at a telephone test desk may apply a high tone of varying loudness to a line to call a subscriber's attention to the fact that his or her receiver is off the hook.

howling—System instability caused by acoustic feedback from loudspeaker to microphone.

howl repeater—In the operation of telephone repeaters, a condition in which more energy is returned than is sent, with the result that an oscillation is set up on the circuit.

hp—Abbreviation for horsepower.

H-pad—An attenuation network in which the elements are arranged in the form of the letter H.

h-parameters—See hybrid parameters.

h-particle—The positive hydrogen ion or proton resulting from bombardment of the hydrogen atom by alpha rays or fast-moving positive ions.

HPF—Abbreviation for highest probable frequency.

H-plane—The plane in which the magnetic field of an antenna lies. It is perpendicular to the E-plane. The principal H-plane of an antenna is the H-plane that also contains the direction of maximum radiation.

H-plane bend—See H-bend.

H-plane T-junction—Also called shunt T-junction. A wavelength T-junction in which the structure changes in the plane of the magnetic field.

HRC—Abbreviation for horizontal redundancy checking. A validity-checking technique used on data-transmission blocks, in which redundant information is included with the information to be checked.

H-scan—See H-display.

HTL—Abbreviation for high-threshold logic.

HTML—Abbreviation for Hypertext Markup Language. The coding language used to create hypertext documents for use on the World Wide Web. HTML allows a document to contain links to another document, giving WWW its hypertext capabilities.

HTML page—A single file document written in HTML. Although this page may require multiple pages of paper if printed, it is typically viewed as a single scrolled page in a web browser.

HTTP—Abbreviation for Hypertext Transfer Protocol. A client/server networking protocol for retrieving HTML documents on the World Wide Web. The client software application used in HTTP transactions is a web browser.

hub—1. On a control panel or plugboard, a socket or receptacle into which an electrical lead or plug wire may be connected for the purpose of carrying signals. 2. The narrow spindle around which the tape is wound on a reel

or in a cassette. 3. Local distribution center where signals from a master feed are relayed to other inputs.

hue—1. Often used synonymously with the term *color*, but does not include gray. It is the dominant wavelength—i.e., the one that distinguishes a color as red, yellow, etc. Varying saturations may have the same hue. 2. A more inclusive and more precise identification of the optical wavelengths than the commonly used word *color*. Rather than state that the maximum daylight sensitivity of the eye is to green-yellow or yellow-green, it is technically more rigorous to state that it occurs at a hue of 555 nanometers. 3. The perceptual term for that aspect of color described by words such as red, yellow, or blue. Achromatic colors, such as white, gray, and black, do not exhibit hue. 4. In color TV, one of the three characteristics of color. Defines color on the basis of its position in the frequency spectrum, i.e., whether red, blue, green, or yellow, etc. See also luminance; saturation.

hue control—On a color television receiver, the operating control that changes the hue (color) of the picture.

hull potential—The voltage difference between a reference electrode and an immersed metallic hull, or the bonded underwater metallic appendages of a nonmetallic hull.

hum—1. In audio-frequency systems, a low-pitched droning noise consisting of several harmonically related frequencies. It results from an alternating-current power supply, ripple from a direct-current power supply, or induction from exposure to a power system. By extension, the term is applied in visual systems to interference from similar sources. 2. A pattern produced on a facsimile record sheet when a signal at the power-line frequency or a harmonic of the power-line frequency is mixed with or modulates the facsimile signal. 3. A continuous low-frequency interference caused by inadvertent pickup of 60-Hz or 120-Hz energy from nearby ac power sources. Most likely to originate in devices (like microphones) requiring substantial amplification. 4. A background tone caused by improper shielding of audio components or inadequate filtering of line voltage entering the equipment. 5. Electrical disturbance at the power supply frequency or harmonics thereof.

human engineering—1. The science and art of developing machines for human use, giving consideration to the abilities, limitations, habits, and preferences of the human operator. 2. The determination of man's capabilities and limitations as they relate to the equipment or systems he will use, and the application of this knowledge to the planning, design, and testing of man-machine combinations to obtain optimum performance, operability, reliability, efficiency, safety, and maintainability. 3. The study of the behavioral properties of humans in interaction with machines, and of total human-machine systems; the structuring of human-machine systems to enhance system performance.

human factors—A body of scientific facts about human characteristics. The term covers biomedical and psychosocial considerations in the areas of human engineering, personnel selection, training, life support, job performance aid, and human-performance evaluation.

humanoid—Robot in the form of a person.

hum-balancing pot—A potentiometer usually placed across the heater circuit. Its arm is grounded so that the heater voltage is balanced with respect to ground.

hum bar—A dark band extending across the picture. It is caused by excessive 60-Hz hum (or harmonics) in the signal applied to the picture-tube input.

hum bars—Relatively broad horizontal bars, alternately black and white, that extend over an entire TV picture. They may be stationary or may move up and

down. Sometimes referred to as a venetian-blind effect, they are caused by an approximate 60-Hz interfering frequency or one of its harmonic frequencies.

hum-bucking — The introduction of a small amount of voltage, at the power-line frequency, into a circuit to cancel unwanted power.

hum-bucking coil — A coil wound around the field coil of a dynamic speaker and connected in series opposition with the voice coil. In this way, any hum voltage induced in the field coil will be induced in the voice coil in the opposite direction and will buck, or cancel, the effects of the hum.

humidity — 1. An indication of the water-vapor content of a gas mixture. 2. The amount of moisture in the air. Measured in percent relative humidity.

humidity transducer — A layer of hygroscopic (moisture-absorbing) substance deposited between two metal electrodes. These electrodes establish electrical contact with the hygroscopic chemical, which serves as a resistance element. Since the chemical coating tends to absorb moisture from the surrounding air, its resistance decreases as the humidity increases. In this manner, humidity variations are converted to resistance variations.

hum loop — A condition arising from the connection of two or more grounds to an amplifier system whereby circulating currents of low value at power-line frequency and harmonics are added to the program signals, causing hum to appear in the background.

humming — A sound produced by transformers having loose laminations or by magnetostriction effects in iron cores. The frequency of the sound is twice the power-line frequency.

hum modulation — Modulation of an rf signal or detected audio-frequency signal by hum. This type of hum is heard only when the receiver is tuned to a station.

hunting — 1. Continuous, cyclical searching by a control system for a desired or ideal value. Rapid hunting usually is termed oscillation; slower cycling is called bird-dogging. 2. Movements of a selector from terminal to terminal until an idle one is found.

HV — Abbreviation for high voltage.

H-vector — A vector that represents the magnetic field of an electromagnetic wave. In free space, it is perpendicular to the E-vector and the direction of propagation.

H-wave — A mode in which electromagnetic energy can be transmitted in a waveguide. An H-wave has an electric field perpendicular to the length of the waveguide, and a magnetic field parallel as well as perpendicular to the length.

hybrid — 1. An electronic circuit that contains both vacuum tubes and transistors. 2. A mixture of thin-film and discrete integrated circuits. 3. A computer that has both analog and digital capabilities. 4. See hybrid junction. 5. A transformer or combination of transformers or resistors that affords paths to three branches, A, B, and C, so arranged that A can send to C, and B can receive from C, but A and B are effectively isolated. 6. A mixture or combination of two different technologies. 7. Made up of several different components. 8. A telephone circuit that joins a two-wire line to a four-wire line. Originally, hybrids were transformers, but today they are electronic circuits. 9. In telecommunications, a circuit that divides a signal transmission channel into two channels (i.e., one for each direction) or, conversely, combines two channels into one.

hybrid arrangement — On a telephone system, the use of hybrid-type transformers with carrier circuits or two-wire repeaters to amplify conversations in both directions without causing feedback or singing effects.

hybrid balance — A measure of the degree of balance between two impedances connected to two conjugate sides of a hybrid set. Given by the formula for return loss. The better the balance, the greater is the transhybrid loss.

hybrid circuit — 1. A circuit that combines the thin-film and semiconductor technologies. Generally, the passive components are made by thin-film techniques, and the active components by semiconductor techniques. The active devices are attached to the thin-film passive components by a suitable bonding process. 2. Also called two-wire-four-wire terminating set. In telephone transmission circuits, a circuit for interconnecting two-wire and four-wire circuits through a differential balance or bridge circuit in which the two sides of the four-wire circuit form conjugate arms. 3. Any circuit made by using a combination of the following component manufacturing technologies: monolithic IC, thin film, thick film, and discrete component. 4. An integrated microelectronic circuit in which each component is fabricated on a separate chip or substrate, interconnected by means of lead wires so that each component can be independently optimized for performance. Example: a circuit package composed of transistor and diode dice, capacitor chips, and thick-film resistors and conductors.

hybrid coil — Also called bridge transformer. 1. A single transformer that has, effectively, three windings and that is designed to be connected to four branches of a circuit so as to render these branches conjugate in pairs. 2. A four-winding transformer used at the junction between a two-wire and a four-wire circuit. It effectively separates the transmit and receive paths. 3. A hybrid consisting of a three-winding tapped transformer used with a balancing network to convert a four-wire telephone line to a two-wire line.

hybrid computer — 1. A computer that results from the interconnection of an analog computer and a digital computer, plus conversion equipment, each contributing its special advantages to an assigned part of the solution of a class of complex problems. 2. A computer that combines both analog and digital equipment for purposes of solving problems that cannot be adequately or economically handled by either type of computer operating independently. The term does not denote the use of some analog equipment to preprocess data that is then converted to digital form and subsequently entered into a conventional digital computer. Rather, there is usually a continual flow of data in both directions between analog and digital equipment. 3. A computer for data processing in which both analog and discrete representations of data are used. 4. A computer designed with both digital and analog characteristics, combining the advantages of analog and digital computers when working as a system.

hybrid electromagnetic wave — Abbreviated HEM wave. A wave in the electromagnetic spectrum that has both electric and magnetic field vectors in the direction of propagation.

hybrid electromechanical relay — A relay with isolated input and output in which electromechanical and electronic devices such as a solid-state amplifiers are combined to perform a switching function with an electromechanical output.

hybrid integrated circuit — Abbreviated HIC. 1. An integrated circuit combining parts made by a number of techniques, such as diffused monolithic portions, thin-film elements, and discrete devices. 2. An arrangement consisting of one or more integrated circuits in combination with one or more discrete passive devices. Alternatively, the combination of more than one type of integrated circuit into a single integrated component. Hybrid ICs offer more circuit complexity than can be achieved with present-generation monolithic ICs. 3. A

composite of either monolithic integrated circuits or discrete semiconductor device circuits, in a unit-packaging configuration. 4. The physical realization of electronic circuits or subsystems from a number of extremely small circuit elements electrically and mechanically interconnected on a substrate. 4. The combination of thin-film or thick-film circuitry deposited on a substrate with chip transistors, capacitors, and other components. Thin-film construction is used for microwave integrated circuits (MICs).

hybrid junction—1. A transformer or waveguide circuit having four terminals (or four ports) so arranged that a signal entering at one terminal will divide and emerge from the two adjacent terminals but will be unable to reach the opposite terminal. Hybrid junctions (quadrature hybrids) are widely used in microwave circuits as power dividers and combiners (e. g., in balanced amplifiers, double-balanced mixers). 2. Also called hybrid tee or magic tee. A waveguide arrangement with four branches. When they are properly terminated, energy is transferred from any one branch into two of the remaining three branches. In common usage, this energy is divided equally between the two. 3. Any network or device that provides a low impedance path and impedance matching between adjacent circuits, but maintains a high degree of isolation between opposite circuits. Several types are common: (a) a three-winding hybrid transformer, (b) a resistance bridge circuit, and (c) a waveguide device known as a hybrid tee.

hybrid loss—The transmission loss incurred when a signal goes through a hybrid coil. This loss is about 3.6 dB (3 dB because the current divides into two equal halves, and 0.6 dB for coil loss).

hybrid microcircuit—A circuit produced by the combination of several different components in a single package. Hybrids form a middle ground between boards or modules using packaged components and monolithic ICs, which may not offer sufficient performance. Hybrids are commonly formed from a combination of chip or packaged active devices and thin- or thick-film passive devices.

hybrid microelectronics—The entire body of electronic art that is connected with or applied to the realization of electronic systems using hybrid circuit technology.

hybrid network—A nonhomogeneous communication network required to operate with signals of dissimilar characteristics (such as analog and digital modes).

hybrid parameters—Also called h-parameters. The resultant parameters of an equivalent transistor circuit when the input current and output voltage are selected as independent variables.

hybrid ring—Also called a rat race. A hybrid junction commonly used as an equal power divider. It consists of a reentrant line (waveguide) to which four side arms are connected. The line is of the proper electrical length to sustain standing waves.

hybrids—A particular type of circuit or module consisting of a combination of two or more integrated circuits, or one integrated circuit and discrete elements. See hybrid integrated circuit.

hybrid set—Two or more transformers interconnected to form a network having four pairs of accessible terminals. Four impedances may be connected to the four terminals, so that the branches containing them may be made conjugate in pairs.

hybrid solid-state relay—A relay with isolated input and output in which electromechanical and electronic devices are combined to perform switching functions with a solid-state output. Typically, a reed switch is used to trigger a solid-state output device.

hybrid tee—See hybrid junction, 2.

hybrid thin-film circuit—A microcircuit formed by attaching discrete components and semiconductor devices to networks of passive components and conductors that have been vacuum deposited on glazed ceramic, sapphire, or glass substrates.

hybrid transformer—See hybrid coil.

hybrid-type circuit—See hybrid integrated circuit; multichip circuit.

hydraulic robot—Programmable machine that uses hydraulic motors and cylinders such as pneumatic robots use pneumatic motors and cylinders. In most cases these motors and cylinders are controlled by servo valves, a system that permits smooth motion as well as high lifting capacity. However, some hydraulic robots control their motors and cylinders with mechanical stops.

hydroelectric—The production of electricity by water power.

hydrogen electrode—A platinum electrode covered with platinum black, around which a stream of hydrogen is bubbled. The hydrogen electrode furnishes a standard against which other electrode potentials can be compared.

hydrogen lamp—A special light source, used in some spectrophotometers, that produces invisible light energy. It is used in finding the light-energy frequency of test solutions.

hydrogen thyratron—A thyratron containing hydrogen.

hydrolysis—The chemical decomposition of a substance in the presence of water. Usually, it is considered in the sense of chemical degradation of insulating materials under the influence of heat or pressure and in contact with moisture (for example, hydrolysis of polyester films and coatings).

hydromagnetics—See magnetohydrodynamic power generator.

hydromagnetic waves—Waves in which the energy oscillates between the magnetic field energy and kinetic energy of the hydrodynamic motion, the reservoirs being the self-inductance of the conductive matter and the mass inertia of the moving fluid.

hydrometer—An instrument for determining the specific gravity of liquids, especially of a storage-battery electrolyte. It consists of a weighted glass float having a graduated stem that sinks into the liquid to a point determined by the specific gravity of the liquid. The float is usually contained in a glass, and a rubber syringe is used to withdraw a sample of the liquid.

hydrophone—An electroacoustic transducer that responds to waterborne sound waves and delivers essentially equivalent electric waves.

hydrostatic pressure—See static pressure.

hygrometer—An instrument that measures the relative humidity of the atmosphere.

hygroscopic—Readily capable of absorbing and retaining moisture from the atmosphere. The opposite term is nonhygroscopic.

hygrostat—A device that closes a pair of contacts when the humidity reaches a prescribed level.

hyperbola—1. A curve that is the locus of points having a constant difference of distance from two fixed points. 2. In hyperbolic guidance systems, a path along which the difference between the arrival times of pulses from two transmitters is constant. See also hyperbolic guidance system.

hyperbolic error—The error in an interferometer system arising from the assumption that the directions of the wavefronts incident at two antennas of a base

line are parallel, whereby the equiphase path is a cone. Mathematically the equiphase path is a hyperbola.

hyperbolic grind—A shape of tape playback and record heads. It permits good head contact and better response at high frequencies.

hyperbolic guidance system—A method of guidance in which sets of ground stations transmit pulses from which a hyperbolic path can be derived to give range and course information for steering. *See also* hyperbola.

Hyperbolic guidance.

hyperbolic head—A recording head whose pole-piece surfaces (when viewed from the edge of the tape) are shaped like the graph of a mathematical hyperbolic function. This shape offers a good compromise between intimate tape contact at the gap and proximity to the tape of the rest of the pole-piece face (the latter is necessary for good low-frequency response).

hyperbolic horn—A horn in which the equivalent cross-sectional radius increases according to a hyperbolic law.

hyperbolic navigation system—A method of radionavigation (e.g., loran) in which pulses transmitted by two ground stations are received by an aircraft or ship. The difference in arrival time from each station is a measure of the difference in distance between the aircraft or ship and each station. This distance is plotted on one of many hyperbolic curves on a map. A second reading from another pair of stations (or from the same master and a different slave) establishes another point on a different hyperbolic curve. The intersection of the two curves gives the position of the aircraft or ship.

hyperboloidal subreflector—The secondary reflector used in a Cassegrain antenna system. The surface has a hyperbolic shape.

HyperCard—A software tool introduced by Apple computer in 1987 to provide new ways to organize, display, and navigate through data that broadened the capability of the Macintosh computer so noncomputer programmers could design and write their own computer applications.

hyperfocal distance—That object distance at which a camera must be focused so that the far depth of field just extends to infinity. The near limit of the depth of field is then half the hyperfocal distance. For normal photographic work this distance equals 1000 times the lens aperture diameter.

hyperfrequency waves—Microwaves having wavelengths in the range from 1 centimeter to 1 meter.

hyperlink—On a computer screen, a colored section of text (usually blue) that, when clicked, takes one to another web page.

hypersensor—A single-component, reset-table circuit breaker that operates as a majority-carrier tunneling device. It is used to provide overcurrent or overvoltage protection of integrated circuits.

hypersonic—Having five or more times the speed of sound.

hypertext—1. A concept for organizing information made possible by computers, in which keywords or phrases not only reference additional resources but also serve as software links to these resources. When viewing an HTML document with a browser, hypertext links or anchors are displayed (usually in blue) as underlined text. Clicking on this text immediately establishes a network connection to another file (or another place in the same file) containing more information on the underlined subject, and causes the browser to display this information. The other file can be anywhere on the Internet, and may contain almost anything including text, images, movies, or sounds. 2. A system that allows documents to be cross-linked in such a way that the reader can explore related documents by clicking on a highlighted word or symbol. 3. Generally, any text that contains links to other documents—words or phrases in the document that, when selected by a reader, cause another document to be retrieved and displayed.

hypersyn motor—A synchronous motor that combines the desirable features of the induction, hysteresis, and dc-excited synchronous motor, resulting in high efficiency and power factor. It possesses the vigorous starting torque of an induction motor, the synchronization torque of a hysteresis motor, and the stiffness of an externally dc-excited synchronous motor.

hysteresigraph—A device for experimentally presenting or recording the hysteresis loop of a magnetic specimen.

hysteresis—1. A property of all magnetic materials that causes the value of magnetic flux density to lag behind the change in value of the magnetizing force that produces the flux. It is caused by the reluctance of the molecules to change their orientation. Work done to move the molecular magnets is a loss and appears in the form of heat. 2. A type of oscillator behavior in which multiple values of the output power and/or frequency correspond to given values of an operating parameter. 3. The temporary change in the counting rate-versus-voltage characteristic of a radiation-counter tube (caused by previous operation). 4. The difference between the response of a unit or system to an increasing and a decreasing signal. 5. A form of nonlinearity in which the response of a circuit to a particular set of input conditions depends not only on the instantaneous values of those conditions, but also on the immediate past (recent history) of the input and output signal. Hysteretical behavior is characterized by inability to retrace exactly on the reverse swing a particular locus of input/output conditions. 6. The lag in the response of an instrument or process when a force acting on it changes abruptly. 7. The property of a magnetic material by virtue of which the magnetic induction for a given magnetizing force depends on the previous conditions of magnetization. 8. This term literally means to lag behind.

It is quite often used to describe the residual effect that remains after the primary effect has been removed, or the lag that exists between the responding parameter and the changing parameter. It can be seen in stress-strain and magnetizing-force magnetic-field relationships. 9. A tendency for a display element to stay in either the on or off condition once it has been switched. With hysteresis, for example, a sustaining voltage can be applied to a display to keep all lighted pixels glowing without lighting any that are supposed to be off.

hysteresis brake — See hysteresis clutch.

hysteresis clutch — Also called hysteresis brake.

A proportional torque-control device that employs the hysteresis effect in a permanent-magnet rotor to develop its output torque. It is capable of synchronous driving or continuous slip, provided heat can be removed, with almost no torque variation at any slip differential. Its control-power requirement is small enough for vacuum-tube or transistorized drive.

hysteresiscope — An instrument used to obtain hysteresis loops on a cathode-ray oscilloscope screen without the need for specially prepared ring samples. It is used in the inspection of magnetic material.

hysteresis curve — 1. A curve showing the relationship between a magnetizing force and the resultant magnetic flux. 2. A graph showing the amount of magnetism imparted to a magnetizable material as the result of a varying magnetic field. This coincides with the variations of the applied field only through a relatively narrow range between zero magnetism and saturation, but the addition of a bias allows an audio signal to be recorded on a magnetic tape within this linear range, for minimum distortion.

hysteresis distortion — Distortion of waveforms in circuits containing magnetic components. It is due to the hysteresis of the magnetic cores.

hysteresis error — The difference in the reading obtained on a measuring instrument containing iron when the current is increased to a definite value and when the current is reduced from a higher value to the same definite value.

hysteresis heater — An induction device in which a charge (or a muffle around the charge) is heated by hysteresis losses due to the magnetic flux produced in the charge.

hysteresis loop — 1. A curve (usually with rectangular coordinates) that shows, for a magnetic material in a cyclically magnetized condition, two values of the magnetic induction for each value of the magnetizing force: one when the magnetizing force is increasing, the other when it is decreasing. 2. The graphical representation of

Hysteresis loop.

relationship between the magnetizing force and the resultant induced magnetization of a ferromagnetic material when the magnetizing field is carried through a complete cycle of equal and opposite values under cyclic conditions.

hysteresis loss — 1. The power expended in a magnetic material as a result of magnetic hysteresis. 2. The power dissipated in a ferromagnetic core as a result of its hysteresis; proportional to the product of the area of the loop, times the frequency, times the volume of the core. 3. Loss that occurs when a rapidly changing current, such as ac, is forced to continually supply energy to an iron core that tends to “memorize” previous magnetic states. 4. The power loss in a magnetic core, such as in a transformer energized by an alternating current, that is due to hysteresis.

hysteresis meter — An instrument for determining the hysteresis loss in a ferromagnetic material. It measures the torque produced when the test specimen is placed in a rotating magnetic field or is rotated in a stationary magnetic field.

hysteresis motor — A synchronous motor without salient poles or direct-current excitation. It is started by the hysteresis losses induced in its secondary by the revolving field.

hysteroscope — An instrument used to observe, measure, and record the magnetic characteristics of both easy and hard axes of magnetic materials.

Hz — Letter symbol for hertz, meaning cycles per second (of any periodic phenomenon).

I

I—1. Symbol for current. 2. Abbreviation for luminous intensity.

IACS—Abbreviation for International Annealed Copper Standard. A standard of copper conductivity by specifying resistivity and temperature.

IBM card—A type of paper card that may have information recorded on it by means of punched holes and that may be read by a computer.

IC—1. Abbreviation for integrated circuit. 2. Abbreviation for internal connection.

***I*_{CBO}**—The reverse current that occurs when a specific dc voltage is applied in the nonconducting direction to the collector junction of a transistor while the emitter is open-circuited.

ICE—Abbreviation for in-circuit emulator and in-circuit emulation.

ice loading—The weight of ice an antenna can accumulate without being damaged.

icon—A small picture displayed on a computer screen that represents a command or an object that can be manipulated by the user. Usually, the picture shows what the icon does. For example, the PRINT icon generally looks like a printer.

iconoscope—A camera tube in which a beam of high-velocity electrons scans a photoemissive mosaic capable of storing an electrical charge pattern.

IC socket—Female contact that provides pluggable electrical engagement on its inner surface for integrated circuit components to achieve interfacing to a printed circuit board.

ICW—Abbreviation for interrupted continuous wave.

ID—Abbreviation for inside diameter.

ideal bunching—A theoretical condition in which bunching of the electrons in a velocity-modulated tube would give an infinitely large current peak during each cycle.

ideal capacitor—A capacitor having a single-valued transferred-charge characteristic.

ideal crystal—A crystal having no mosaic structure and capable of X-ray reflection in accordance with the Darwin-Ewald-Prins law.

ideal dielectric—A dielectric in which all the energy required to establish an electric field in the dielectric is returned to the source when the field is removed. (A perfect dielectric must have zero conductivity. Also, all absorption phenomena must be lacking. A vacuum is the only known perfect dielectric.)

ideal filter—Any filter in which the range of frequencies within a chosen radius suffers no attenuation and the range of frequencies outside the radius is entirely attenuated.

ideal-noise diode—A diode that has an infinite internal impedance and in which the current exhibits full shot-noise fluctuations.

ideal transducer—Theoretically, any linear passive transducer that—if it dissipated no energy and, when connected to a source and load, presented its combined impedance to each—would transfer maximum power from source to load.

ideal transformer—A hypothetical transformer that would neither store nor dissipate energy. Its self-inductances would have a finite ratio and unity coefficient of coupling, and its self- and mutual impedances would be pure inductances of infinitely great value.

Idemodulator—A demodulator circuit whose inputs are the chrominance signal and the signal from the local 3.58-MHz oscillator. The output of this demodulator is a video signal representing color in the televised scene. The Q demodulator is similar except that its input from the local oscillator is shifted 90°.

identification—1. In radar, determining the identity of a displayed target (i.e., which one of the blips in the display represents the target). 2. In a computer, a code number or code name that uniquely identifies a record, block, file, or other unit of information.

identification beacon—A code beacon used for positively identifying a particular point on the earth's surface.

identification, friend or foe—Abbreviated IFF. A system using radar transmissions to which equipment carried by friendly forces automatically responds, for example, by emitting pulses, thereby distinguishing themselves from enemy forces. It is the primary method of determining the friendly or unfriendly character of aircraft and ships by other aircraft or ships and by ground forces employing radar-detection equipment and associated IFF units.

identifier—1. A symbol whose purpose is to identify, indicate, or name a body of data. 2. A mnemonic code used to identify or name an item of data or data format in a computer.

identify—In a computer, to attach a unique code or code name to a specific unit of information.

idichromatic—Having photoelectric properties characteristic of the pure crystal itself and not due to foreign matter.

I-display—In radar, a display in which a target appears as a circle when the radar antenna is pointed directly at it. The radius of the circle is proportionate to the target distance. When the antenna is not pointing at the target, only a segment of the circle appears. Its length is inversely proportional to the magnitude of the pointing error, and the segment points away from the direction of error.

idle characters—Control characters interchanged by a synchronized transmitter and receiver to maintain synchronization during a nondata period.

idle noise—1. Noise that exists in a communication system when no signals are present. 2. Unwanted, random

electrical energy present in a transmission system under unmodulated conditions.

idler—1. A rubber-tired wheel that transfers power from a phonograph motor to the turntable rim. 2. An intermediate drive wheel, usually with a rubber or neoprene "tire," that transfers rotational energy from a driven wheel to a third wheel. Often used for speed reduction between a drive motor and capstan shaft. *See also* pinch roller.

idler drive—1. A drive system used to rotate a turntable, which consists of a drive-shaft that is turned by the motor pulley and that drives the inside rim of the turntable platter. 2. A system for transferring power from a motor to a turntable through a rubber wheel that contacts the motor shaft and the inside rim of the platter.

idler frequency—A sum or difference frequency, other than the input, output, or pump frequencies, generated within a parametric device and requiring specific circuit consideration to achieve the desired performance of the device.

idler pulley—A pulley used only for tightening a belt or changing its direction. The shaft does not drive any other part.

idle time—That portion of available time during which the hardware is not in use.

idle-trunk lamp—A signal lamp that indicates that the outgoing trunk with which it is associated is not busy.

idling current—Also called quiescent current. The zero-signal power supply current drawn by a circuit or by a complete amplifier.

IDT—Abbreviation for interdigital transducer.

IEC—1. Abbreviation for integrated electronic component. 2. Abbreviation for International Electrotechnical Commission. An organization that cooperates with the ISO for technology standards.

IEEE—Abbreviation for Institute of Electrical and Electronic Engineers. A professional organization of scientists and engineers whose purpose is the advancement of electrical engineering, electronics, and allied branches of engineering and science. (The IEEE resulted from the merger of the IRE and the AIEE.)

IEEE-488 bus—Also known as the general-purpose interface bus (GPIB). 1. An interface standard that defines digital data exchange between up to 15 instruments; a bus widely used to connect test instrumentation. 2. An industry-standard bus that defines a digital interface for programmable instrumentation; it uses a byte-serial, bit-parallel technique to handle 8-bit-wide data words. Published by the IEEE in 1975, revised 1978.

IEM—Abbreviation for illuminated entry module. An electronic convenience control (offered by Ford Motor and General Motors) that lights up a car's interior and door keyhole slots for a timed interval of about 20 seconds while the car owner unlocks the door.

IF—Abbreviation for intermediate frequency.

IF amplifier—*See* intermediate-frequency amplifier.

IF bandwidth—The range of frequencies centered about the intermediate frequency limited by the -3 -dB amplitude points.

IF canceler—In radar, a moving-target-indicator canceler operating at intermediate frequencies.

IFF—*See* identification, friend or foe.

IF rejection—The ability of a superheterodyne AM or FM tuner's IF circuits to reject external interference at the intermediate frequency. Measured in decibels (the higher the better), it is of more significance in AM than in FM reception because the lowest broadcast AM frequency, now 530 kHz, is so close to the standard AM intermediate frequency of 455 kHz.

IFRU—*See* interference-rejection unit.

IF selectivity—The ability of the IF stages of a superheterodyne receiver to accept the signal from one

station while rejecting the signal of the adjacent stations; it is the ratio of desired to undesired signal required for 30-dB suppression of the undesired signal (IHF standard).

if statement—*See* conditional statement.

IF strip—*See* intermediate-frequency strip.

IF transformer—*See* intermediate-frequency transformer.

IGFET—Abbreviation for insulated-gate field-effect transistor. Though a less popular term than MOS (metal-oxide semiconductor), it more precisely defines devices made by various MOS processes. *See also* metal-oxide semiconductor field-effect transistor.

ignition cable—Cable designed primarily for automotive ignition systems.

ignition coil—1. An iron-core transformer that converts a low direct voltage to the 20,000 volts or so required to produce an ignition spark in gasoline engines. It has an open core, a heavy primary winding connected to the battery or other source through a vibrating armature contact, and a secondary winding with many turns of fine wire. 2. That part of the ignition system which acts as a transformer to step up the battery voltage to many thousands of volts. The high-voltage surge then produces a spark at the spark-plug gap.

Ignition coil.

ignition control—Control of the instant that static current begins to flow in the anode circuit of a gas tube.

ignition interference—Noise produced by sparks or other ignition discharges in a car, motor, or furnace ignition, or by equipment with loose contacts or connections.

ignition reserve—In a gasoline engine, the difference between the available voltage and the required ignition voltage.

ignition system—In an automobile, the system that furnishes high-voltage sparks to the engine cylinders to fire the compressed air-fuel charges. It consists of battery, ignition coil, ignition distributor, ignition switch, wiring, and spark plugs.

ignition terminal—Solderless terminal designed for use in automotive ignition work.

ignition voltage—In a gasoline engine, the peak voltage required to produce a spark across the plug electrodes.

ignitor discharge—In switching tubes, a dc glow discharge between the ignitor electrode and a suitably located electrode. It is used to facilitate radio-frequency ionization.

ignitor electrode—An electrode (which is partly immersed in the mercury-pool cathode of an ignitron) used to initiate conduction at the desired points in each cycle.

ignitor firing time—In switching tubes, the interval between application of a dc voltage to the ignitor electrode and start of current flow.

ignitor interaction—In a tr, pre-tr, or attenuator tube, the difference between the insertion loss measured at a specified level of ignitor current and that measured at zero ignitor current.

ignitor leakage resistance—In a switching tube, the insulation resistance measured between the ignitor electrode terminal and the adjacent rf electrode in the absence of an ignitor discharge.

ignitor oscillation—A relaxation type of oscillation in the ignitor circuit of a tr, pre-tr, or attenuator tube.

ignitor voltage drop—In switching tubes, the dc voltage between the cathode and anode at a specified ignitor current.

ignitron—A type of mercury-pool rectifier that has only one anode. The arc is started for each cycle of operation by an igniter that dips into the mercury pool. The mercury pool serves as the cathode of the rectifier. The ignitron is characterized by the ability to withstand tube currents several times as high as rated values for a few cycles.

Ignitron.

ignore—In a computer, a character code indicating that no action is to be taken.

IGY—Abbreviation for international geophysical year.

IHF—Abbreviation for Institute of High-Fidelity Manufacturers, an association of manufacturers that publishes ratings and standards for high-fidelity equipment.

I²L—Abbreviation for integrated injection logic (pronounced "I-squared L"). 1. A bipolar logic circuit that has a much higher packing density than conventional transistor-transistor logic or complementary metal-oxide semiconductor (CMOS), dissipates low power, and has high-speed characteristics. To an extent it combines bipolar speed, MOS circuit density, and the low-power dissipation of CMOS.

I³L—Abbreviation for isoplanar integrated injection logic (Fairchild Camera & Instrument Corp.).

illegal character—A character or combination of bits that does not have validity according to some criterion; for example, a character that is not a member of a specified alphabet.

illegal operation—An impossible-to-execute computer instruction.

illuminance—1. The density of luminous flux at a given distance from the center of a source. It is equal to the total flux divided by the surface area over which it is uniformly spread. The units of illuminance are

lumens/cm², lumens/ft², etc. One lumen/ft² is the same as a footcandle; one lumen/cm² is the same as one phot; and one lumen/m² is equal to one lux, or one meter-candle.

2. Luminous flux incident per unit area of a surface; luminous incidence. (The use of the term *illumination* for this quantity conflicts with its more general meaning.)

illuminant-C—The reference white of color television—i.e., light that most nearly matches average daylight.

illuminate—1. To expose to light. 2. In radar, to strike with a radar signal so that reflection returns the signal to the source for interpretation.

illuminated—Characteristic of a surface or object that has luminous flux incident on it.

illuminated entry module—See IEM.

illumination—1. The light flux incident on a unit projected area; it is the photometric counterpart of irradiance and is expressed in footcandles. 2. The density of the luminous flux incident on a surface; it is the quotient of the luminous flux by the area of the surface, when the latter is uniformly illuminated (SI unit = lux or lx). 3. The general term meaning the application of light to a subject. Should not be used in place of the specific quantity *illuminance*.

illumination control—A photorelay circuit that turns on artificial lighting when natural illumination decreases below a predetermined level.

illumination sensitivity—The output current of a photosensitive device divided by the incident illumination at constant electrode voltages.

illuminometer—A photometric instrument used to measure the illumination falling on a surface. May be photoelectric or visual.

ILO—See injection-locked oscillator.

ILS—Abbreviation for instrument landing system. A radio beacon system forming a straight pencil beam from the runway that planes can follow from 5 to 7 miles (8 to 12 kilometers) away. An alternative is a microwave landing system.

image—1. The instantaneous illusion of a picture on a flat surface. 2. The unused one of the two groups of sidebands generated in amplitude modulation. 3. A spatial distribution of some physical property (e.g., radiation, electric charge, conductivity, or reflectivity) made to correspond with another distribution of the same or another physical property. 4. A two-dimensional representation of an object or a scene formed by creating a pattern from the light received from the scene.

image admittance—Reciprocal of image impedance.

image antenna—The imaginary counterpart of an actual antenna. For mathematical purposes it is assumed to be located below the ground and symmetrical with the actual antenna.

image-attenuation constant—The real part of the transfer constant.

image compression—The translation of data in any format (such as video or graphics) to a more compact form for storage or transmission such that it takes up less space in a computer's memory.

image converter—1. A solid-state optoelectric device capable of changing the spectral characteristics of a radiant image. Examples of such changes are infrared-to-visible and X-ray-to-visible. 2. An electron tube that employs electromagnetic radiation to produce a visual replica of an image produced on its cathode. Electrons ejected from the photosensitive cathode by the incident radiation are accelerated to and focused upon a fluorescent phosphor screen, thus forming the visual replica. Image converters can be used in the infrared, ultraviolet, and

X-ray regions as well as in the visible. An example of an infrared-sensitive image converter is the snooperscope.

image-converter tube—See image tube.

image dissection—An optical, mechanical, or electronic process, or a combination of such processes, in which an optical image is divided into discrete segments prior to being photographed, recorded, transmitted, or processed in some other way.

image dissector—1. A television camera tube in which the image is swept past an aperture in a series of 525 interlaced lines 30 times per second. Instead of a beam scanning the image, the entire image is scanned past the aperture, which “dissects” the image—hence the name. See also dissector tube. 2. In OCR, a mechanical or electronic transducer that detects in sequence the light levels in different areas of a completely illuminated sample space.

Image dissector, 1.

image dissector tube—An electron tube that is used as a camera tube for a television system. When the picture to be transmitted is focused on a photosensitive surface, electrons are emitted from each section of the surface in proportion to the amount of light in that certain part of the picture, and are then drawn down the tube in a positive anode. However, the electrons are still focused in an electric field. The focusing fields are changed regularly to sweep the electron picture horizontally and vertically as it travels down the tube. The picture then passes through an aperture into an electron multiplier, where the output of the multiplier varies with the different parts of the picture. This output represents the dissecting of the picture into ordered parts.

image distortion—Failure of the reproduced image in a television receiver to resemble the original scene scanned by the camera.

image effect—An effect produced on the field of an antenna as the electromagnetic waves are reflected from the earth’s surface.

image enhancement—Also called detail enhancement. The process by which the image is manipulated to increase the information extracted by the human visual system.

image-enhancing equipment—An elaborate device, often involving a computer, in which a photograph is scanned by a point of light, the amplitude of the electrical signal being modified electronically before being rerecorded on another film.

image force—The force on a charge due to that charge or polarization which it induces on neighboring conductors or dielectrics.

image frequency—1. In heterodyne frequency converters, an undesired input frequency capable of producing the selected frequency by selecting one of the two sidebands produced by beating. The word *image* implies the mirrorlike symmetry of signal and image frequencies about the beating oscillator frequency or intermediate

frequency, whichever is higher. 2. An undesired signal obtained in frequency conversion using a mixing or heterodyning process.

image-frequency rejection ratio—Of a superheterodyne receiver, the ratio of the response at the desired frequency to the response at the image frequency.

image iconoscope—1. An iconoscope in which greater sensitivity is obtained by separating the function of charge storage from that of photoelectric emission. An optical image is projected on a continuous photosensitive screen, and the electron emission from the back of this screen is focused electromagnetically onto a mosaic screen that is scanned by an electron beam as the original emitron cathode-ray tube. The British term is super-emitron. 2. A camera tube similar in design to the iconoscope. However, the image formed in the image iconoscope is projected on a photocathode that emits photoelectrons to be focused on a material, forming the charge image.

image impedance—The impedances that will simultaneously terminate all inputs and outputs of a transducer so that at each of its input and outputs the impedances in both directions are equal.

image intensifier—1. A system for increasing the sensor response to a radiation pattern or image by interposing active elements between the sensor and the image, and supplying power to the active element. This is normally done by focusing the scene to be imaged on the photocathode of the tube, giving rise to a photoelectron pattern corresponding to the optical image. This pattern is accelerated and focused onto a phosphor, which emits light to reproduce a visual image of the scene. 2. Device used in X-ray techniques for brightening the fluoroscopic image several hundred times and reducing radiation exposure. 3. An electronic tube equipped with a light-sensitive electron emitter at one end and a phosphor screen at the other end; an electron lens inside the tube relays the image. This device is used in astronomy and in military and surveillance systems to provide night vision.

image interference—In a receiver, a response due to signals of a frequency removed from the desired signal by twice the intermediate frequency.

image-interference ratio—In a superheterodyne receiver, the effectiveness of the preselector in rejecting signals at the image frequency.

image inverter—A fiber-optic device that rotates an image through a predetermined angle.

image orthicon—1. A camera tube in which a photoemitting surface produces an electronic image and focuses it on one side of a separate storage target. The opposite side of the target is then scanned by low-velocity electrons to produce the output. 2. A camera tube widely used in TV broadcasting. It consists of three sections all included in a single vacuum envelope. The three parts are as follows: (a) A photosensitive film sometimes called the photocathode. The scene to be televised is focused on this film by an outside camera lens. (b) The scanning beam provided by an electron gun, which scans lines of the target film. The gun’s beam is deflected by electromagnets within the tube (the whole picture is scanned by the beam in $1/30$ of a second). (c) A return beam of electrons falls on a multiplier section, where an electron current of sufficient magnitude is developed to be sent out from the broadcast transmitter as a video signal. See Figure on p. 367.

image phase constant—The imaginary part of the transfer constant.

image plane holography—A type of holographic process in which a lens is used to image the subject in the film plane.

Image orthicon.

image ratio—In a heterodyne receiver, the ratio of the image-frequency signal input to the desired signal input for identical amplitude outputs.

image redundancy—The multiple storage of a single image.

image rejection—1. The suppression of image-frequency signals in a superheterodyne receiver. 2. The rejection by the tuner of a signal at the image (second-channel) frequency, corresponding to the tuned (real) frequency plus twice the intermediate frequency when the local oscillator is working above the signal frequency, or minus twice the intermediate frequency when the local oscillator is working below the signal frequency. 3. The ability of a superheterodyne receiver to ignore signals removed from the desired frequency by twice the intermediate frequency (10.7 MHz in home FM receivers, 455 kHz in home AM receivers). Image response can be reduced by using selective tuned stages in the input circuits of the tuner. As with most tuner rejection or suppression specifications, it is measured in decibels, with higher numbers indicating more suppression.

image-rejection ratio—The ratio (in decibels) of the signal required for a 30-dB signal-to-noise ratio to that required for the same ratio but at the image frequency. An increase in front-end selectivity increases the ratio.

image-reject mixer—A combination of two balanced mixers and associated hybrid circuits designed for separation of the image channel from the signal channels normally present in a conventional mixer. The arrangement makes possible image rejection of up to 30 dB without the use of filters.

image response—The response of a heterodyne receiver to a signal that is separated by twice the intermediate frequency from the frequency to which the receiver is tuned. Unless there is some preselection, images will cause spurious unwanted responses when the spectrum occupied by a signal is greater than twice the frequency of the first IF stage of the receiver.

image retaining panel—A type of electroluminescent display that records and maintains an irradiated image on its phosphor screen, provided a dc potential is applied to the screen. Used to record X-ray images, the display can retain an image for up to 30 minutes if the dc potential is maintained.

image retention—The vidicon pickup tube's tendency to retain an image on its target area after it has stopped scanning that image. Extreme image retention results in the image being burned into the target area.

image storage panel—A modified form of an image retaining panel that can be used in subdued daylight. This is achieved by the addition of a layer of zinc oxide between the panel's phosphor layer and its rear electrode. The zinc oxide cannot be made photoconductive by low-intensity daylight, but does become so when exposed to X-rays. An electroluminescent image is obtained by the application of ac voltage to the panel following its exposure to the X-rays.

image transducer—Any arrangement of a bundle of optical fibers that alters the shape of the image. For example, by a systematic regulation of the spacing of the fibers from the entrance end to the exit end, a distortion of the image can occur that may be used to neutralize or compensate for the distortion introduced by the lens, prism, or mirror components in an optical system.

image-transfer constant—See transfer constant.

image tube—Also called an image-converter tube. An electron tube that reproduces on its fluorescent screen an image of an irradiation pattern incident on its photo-sensitive surface.

image-tube camera—A camera system in which the image formed on the fluorescent screen of an image converter tube in the system is recorded by photography, or direct-contact printing from the face of the tube.

imaging—The process of creating and manipulating data for visual presentation and storage.

imbedded layer—A conductor layer deposited between insulating layers.

IMD—See intermodulation distortion.

imitative deception—The transmission of messages in the enemy's communication channels for the purpose of deceiving him or her.

immediate access—The ability of a computer to put data in storage or remove it from storage without delay.

immediate-access store—A store whose access time is negligible compared with other operating times.

immediate addressing—1. In a computer, a mode of addressing in which the operand contains the value to be operated on, and no address reference is required. 2. An addressing mode in which the data for an instruction is the next sequential byte in the instruction stream.

immediate data—Data that immediately follows an instruction in a memory and is used as an operand by that instruction.

immersion plating—1. A method of metal deposition that depends on a galvanic displacement of the metal

being plated by the substrate. Thickness of the plating is limited to 10 to 50 microinches (0.254 to 1.27 μm). 2. The chemical deposition of a thin metallic coating over certain base metals by a partial displacement of the base metal.

immersion pyrometer—An instrument for determining molten-steel temperature and normally consisting of a platinum-platinum rhodium bimetal thermocouple junction and a recording device for transposing the millivoltage into degrees of temperature.

immittance—A term that denotes both impedance and admittance. It is commonly applied to transmission lines, networks, and certain kinds of measuring instruments.

IMOS—See ion-implanted MOS.

impact excitation—The starting of damped oscillations by a sudden surge, such as by a spark discharge.

impact modulator amplifier—A fluidic device in which the impact plane position of two opposed streams is controlled to alter the output.

impact predictor—A device that can determine, in real time, the point on the earth's surface where a ballistic missile will impact if thrust is instantaneously terminated.

impact printer—1. Any type of printer that generates characters by using some form of stamping or inking through a ribbon by some sort of character slug, element, or hammer-needle. (Daisy-wheel printers are impact printers.) 2. Any mechanical imprinting device that forms characters by striking characters against a ribbon onto paper. 3. A mechanical printer operating at relatively low speeds—from 150 lines per minute to 1800 lines per minute. Has multiple copy capability and normally is capable of producing an original plus three copies. Impact printers are identified as letter-quality, dot-matrix, and line-printing types. No longer in common use.

Impact printer (dot-matrix).

impact printing—Printing that is produced by the impact of a key on an inked ribbon, transferring the impression of a character onto the paper located behind the ribbon.

impact resistance—Resistance to fracture under shock force.

IMPATT—Acronym for impact avalanche and transit time.

IMPATT diode—Impact avalanche and transmit time diode. 1. A pn-junction diode operated with heavy back bias so that avalanche breakdown occurs in the active region. To prevent burnout, the device is so

constructed that the active region is very close to a good heat sink. For the same reason, the bias supply must be a constant-current type. 2. A device whose negative resistance characteristic is produced by a combination of impact avalanche breakdown and charge-carrier transit-time effects. Avalanche breakdown occurs when the electric field across the diode is high enough for the charge carriers (holes or electrons) to create electron-hole pairs. With the diode mounted in an appropriate cavity, the field patterns and drift distance permit microwave oscillations or amplification. 3. A semiconductor microwave diode that, when its junction is biased onto avalanche, exhibits a negative resistance over a frequency range determined by the transit time of charge carriers through the depletion region.

IMPATT diode.

IMPATT oscillator—An oscillator in which the active element is an IMPATT diode operating in a negative resistance mode. Dc to rf conversion efficiencies are normally less than 20 percent. Present devices operate above 5 GHz.

impedance—1. The total opposition (i.e., resistance and reactance) a circuit offers to the flow of alternating current at a given frequency; the ratio of the potential difference across a circuit or element of a circuit to the current through the circuit or element. It is measured in ohms, and its reciprocal is called admittance. Symbol: Z . 2. The combination of resistance and reactance. 3. Combined opposition to current resulting from resistance, capacitance, and inductance. 4. The sinusoidal terminal voltage of a circuit divided by the current through it. 5. A speaker's resistance to an alternating current, which varies with frequency. A speaker's rated impedance is usually the value measured at 400 Hz. 6. The opposition to alternating current in a circuit, generally categorized as either high or low, and measured in ohms. 7. The total opposition that a circuit offers to the flow of alternating current or any other varying current at a particular frequency. It is a combination of resistance, R , and reactance, X , measured in ohms.

impedance angle—Angle of the impedance vector with respect to the resistance vector. Represents the phase angle between voltage and current.

impedance at the intermediate frequency—In a mixer semiconductor diode, the impedance measured at the output terminals of a mixer circuit when the device is driven by a local oscillator under specified conditions.

impedance bridge—A device for measuring the combined resistance and reactance of a component part of a circuit.

impedance characteristic—A graph of impedance versus frequency of a circuit or component.

impedance coil—A coil whose inductive reactance is used to hinder the flow of alternating current in or between circuits.

impedance compensator—1. An electric network used with a line or another network to give the impedance of the combination a certain characteristic over a desired frequency range. 2. A circuit that ensures that a transmission line is a proper electrical load for its communicating devices. It is connected in parallel with the devices.

impedance coupling—A method of coupling using an impedance as the coupling device common to both the primary and secondary circuits. This type of coupling is usually limited to audio systems, where high gain and limited bandpass are required.

impedance drop—The vector sum of the resistance drop and the reactance drop. (For transformers, the resistance drop, the reactance drop, and the impedance drop are, respectively, the sum of the primary and secondary drops reduced to the same terms. They are usually expressed in percent of the secondary-terminal voltage.)

impedance ground—An earth connection made through an impedance of predetermined value usually chosen to limit the current of a short-circuit to ground.

impedance irregularities—Breaks or abrupt changes that occur in an impedance-frequency curve when unlike sections of a transmission line are joined together or when there are irregularities on the line.

impedance match—The condition in which the impedance of a component or circuit is equal to the internal impedance of the source or the surge impedance of a transmission line, thereby giving maximum transfer of energy from sources to load, minimum reflection, and minimum distortion.

impedance matching—1. The connection across a source impedance of another impedance having the same magnitude and phase angle. If the source is a transmission line, reflection is thereby avoided. 2. The process of adjusting the impedances of a load and of its power source so that they are equal. This permits the greatest possible transfer of power. 3. Making the impedance of a terminating device equal to the impedance of the circuit to which it is connected in order to achieve optimum signal transfer.

impedance-matching transformer—A transformer used to match the impedance of a source and load.

impedance plethysmograph—An instrument used to detect the increased blood volume in the tissues of the body during a contraction of the heart. *See also* electrical-impedance cephalography; finger plethysmograph.

impedance transformer—A transformer that transfers maximum energy from one circuit to another.

impedance triangle—A diagram consisting of a right triangle. The sides are proportional to the resistance and reactance in an ac circuit, with the hypotenuse representing the impedance.

imperfect dielectric—A dielectric in which part of the energy required to establish its electric field is converted into heat instead of being returned to the electric system when the field is removed.

imperfection—In a crystalline solid, any deviation in structure from an ideal crystal (one that is perfectly periodic in structure and contains no foreign atoms).

implantable pacemaker—A miniature pulse generator surgically implanted beneath the skin and provided with output leads that connect directly to the heart muscle. The electrodes may contact either the outer wall of the

impedance characteristic — impulse excitation

heart muscle (myocardial electrodes) or the inner surface of the heart chamber (endocardiac electrodes).

implied AND—Also called dot AND or wired AND. A logic element in which the combined outputs are true if and only if all outputs are true. (Sometimes improperly called dot OR or wired OR.)

implied OR—Also called wired OR. A logic element in which the combined outputs are true if one or more of the outputs are true.

implode—The inward bursting of a picture tube due to its high vacuum.

import—To copy data created by one computer program or file into another.

impregnant—1. A substance, usually a liquid, used to saturate the paper dielectric of a capacitor and replace the air between its fibers, thereby increasing the dielectric strength and the dielectric constant of the capacitor. 2. A substance intended to replace the air as dielectric between the electrodes of a capacitor.

impregnate—1. To fill voids and air spaces (of a capacitor or transformer) with a material having good insulating properties commonly called an impregnant. 2. To fill the voids and interstices of a material with a compound. This does not imply complete fill or complete coating of the surfaces by a hole-free film.

impregnated coils—Coils that have been permeated with an electric grade varnish or other protective material to protect them from mechanized vibration, handling, fungus, and moisture.

impregnating—Complete filling of even the smallest voids in a component or closely packed assembly of parts. Low-viscosity compounds, usually liquids, are used. The process is frequently accomplished by a vacuum process in which all air is removed before introducing the impregnating material. Typical examples of impregnating are the filling of capacitors or transformer windings.

impregnation—1. The process of coating the insides of coils and closely packed electronic assemblies by dipping them into a liquid and letting it solidify. 2. The process of completely filling all interstices or a part or assembly with a thin, liquid, electrically insulating material. The process is best accomplished by first removing all air (creating a vacuum), then introducing the impregnant, and finally applying atmospheric or elevated pressures to completely force-fill the system.

impressed voltage—The voltage applied to a circuit or device.

improvement threshold—A characteristic of FM radio receivers that determines the minimum rf signal power required to overcome the inherent thermal noise. For increasing values of rf power above this point, an improvement of signal-to-noise ratio is obtained.

impulse—1. A pulse that begins and ends within so short a time that it may be regarded mathematically as infinitesimal. The change produced in the medium, however, is generally of a finite amount. 2. A current surge of unidirectional polarity. *See also* pulse.

impulse bandwidth—The area divided by the height of the voltage-response selectivity as a function of frequency. It is used in the calculation of broadband interference.

impulse-driven clock—An electric clock in which the hands are moved forward at regular intervals by current impulses from a master clock.

impulse excitation—Also called shock excitation. 1. A method of producing oscillatory current in which the duration of the impressed voltage is relatively short compared with that of the current produced. 2. The sudden application of a momentary steep-wavefront voltage to a resonant circuit, resulting in a damped oscillation.

impulse frequency—The number of pulse periods per second generated by the dial-pulse springs in a telephone as they rapidly open and close in response to the dialing of a digit.

impulse generator—Also called surge generator. 1. An electric apparatus that produces high-voltage surges for testing insulators and for other purposes. 2. A device that generates a broad energy spectrum by means of a very narrow impulse. Usually generated by discharging a short coaxial or waveguide transmission line. The pulses are discrete and regularly spaced, and are generally variable at a repetition rate from a few pulses per second to a few thousand pulses per second. The output of an impulse generator is specified as the rms equivalent of the peak voltage in dB above 1 microvolt per megahertz. 3. An oscillator circuit that generates electric impulses for synchronizing purposes in a television system. 4. A circuit, typically using a step-recovery diode, used to convert a sinusoidal input to a voltage impulse output. The basic circuit block in both step recovery diode multiples and comb generators.

impulse noise—1. Noise due to disturbances having abrupt changes and of short duration. These noise impulses may or may not have systematic phase relationships. The noise is characterized by nonoverlapping transient disturbance. The same source may produce impulse noise in one system and random noise in a different system. 2. A type of communication-line interference characterized by high amplitude and short duration. 3. An unwanted signal characterized by a steep wavefront.

impulse-noise generator—Equipment for generating repetitive pulses that provide random noise signals uniformly spread over a wide band of frequencies.

impulse pay-per-view—Abbreviated IPPV. A feature of a decoder that allows an authorized subscriber to purchase a one-time scrambled program at will. IPPV shows are selected by a button on the decoder or its remote control.

impulse period—See pulse period.

impulse ratio—The ratio of the flashover, sparkover, or breakdown voltage of an impulse to the crest value of the power-frequency flashover, sparkover, or breakdown voltage.

impulse relay—1. A relay that stores enough energy from a brief impulse to complete its operation after the impulse ends. 2. A relay that can distinguish between different types of impulses, operating on long or strong impulses and not operating on short or weak ones. 3. An integrating relay.

impulse response of a room—The time sequence of signals received at some point in a room due to a sound pulse generated at some other point in the room. It defines the arrival of a sound that has transversed the direct path between source and microphone and the arrivals of the various reflections.

impulse sealing—A heat-sealing technique in which a pulse of intense thermal energy is applied to the sealing area for a very short time, followed immediately by cooling. It is usually accomplished by using an rf heated metal bar that is cored for water cooling, or is of such a mass that it will cool rapidly at ambient temperatures.

impulse separator—Normally called sync separator. In a television receiver, the circuit that separates the synchronizing impulses from the video information in the received signal.

impulse sparkover voltage—The highest value of spark-gap or gas-discharge tube terminal voltage prior to ionization and the flow of discharge current.

impulse speed—The rate at which a telephone dial mechanism makes and breaks the circuit to transmit pulses.

impulse strength—A measure of the ability of insulation to withstand voltage surges on the order of microseconds in duration.

impulse timer—A timing device electrically powered by a synchronous motor, featuring a mechanical stepping device that enables it to advance a predetermined number of degrees within a predetermined time interval, controlling a multiple number of circuits. Said circuits are controlled by individual cams, which program their activity.

impulse train—See pulse train.

impulse transmission—The form of signaling used principally to reduce the effects of low-frequency interference. Impulses of either or both polarities are employed for transmission, to indicate the occurrence of transitions in the signals.

impulse-transmitting relay—A relay in which a set of contacts closes briefly when the relay changes from the energized to the deenergized position, or vice versa.

impulse-type telemeter—A telemeter that employs the characteristics of intermittent electric signals, other than their frequency, as the translating means.

impurity—Also called dopant. 1. A material such as boron, phosphorus, or arsenic added to a semiconductor such as germanium or silicon to produce either p-type or n-type material. Impurities that provide free electrons are called donors and cause the semiconductor material to be n-type. Impurities that accept electrons are called acceptors and cause the material to be p-type. 2. A foreign material present in a semiconductor material, usually in small quantities. Some impurities are unwanted, and great pains are taken to extract them from the material. Others are intentionally added to semiconductor materials as dopants in order to modify their electrical behavior. 3. In semiconductor technology, a material such as boron, phosphorus, or arsenic added in small quantities to a crystal to produce an excess of electrons (donor impurity) or holes (acceptor impurity).

impurity density—The amount of impurity material diffused into a certain volume of semiconductor material used in manufacturing semiconductor devices.

impurity ions—An alien, electrically charged atomic system in a solid; an ion substituted for a constituent atom or ion in a crystal lattice, or located in an interstitial site in the crystal.

impurity level—The energy level existing in a substance because of impurity atoms.

inaccuracy—1. The difference between the input quantity applied to a measuring instrument and the output quantity indicated by that instrument. The inaccuracy of an instrument is equal to the sum of its instrument error and its uncertainty. 2. The term sometimes used to indicate the deviation from an indicated or recorded value or the measure of conformity to an accepted standard.

inactive leg—Within a transducer, an electrical element that does not change its electrical characteristics with the applied stimulus. Applied specifically to elements that complete a Wheatstone bridge in certain transducers.

in-band signaling—1. The transmission of signaling tones at some frequency or frequencies within the channel normally used for voice transmission. 2. A signaling scheme that uses the same path for both data and signaling information.

in-band spurious transmitter output—A spurious transmitter output that lies within the specified band of transmission.

incandescence—1. The state of a body with such a high temperature that it gives off light. 2. The generation

of light caused by passing an electric current through a wire filament. The resistance of the filament to the current causes the filament to heat up and emit radiant energy, some of which is in the visible range.

incandescent lamp—1. An electric lamp in which electric current flowing through a filament of resistance material heats the filament until it glows. 2. A lamp that emits light when an electric current passes through a resistant metallic wire situated in a vacuum tube. 3. An electric lighting and signaling device operating on the principle of heating a fine metal wire filament to a white heat by passing an electric current through it. The filament wire has a positive temperature coefficient, which results in high inrush currents, up to 10 times the steady-state current.

INCH—Acronym for integrated chopper. It is a device designed to operate as a chopper, commutator, modulator, demodulator, or mixer, depending on circuit requirements.

inching—See jogging.

incidence angle—The angle between an approaching light ray or emission and the perpendicular (normal) to the surface in the path of the ray.

incidental FM—Also called residual FM. 1. The short-term jitter or undesired FM deviation of a local oscillator. It limits resolution when it approaches the IF bandwidth in magnitude. 2. Peak-to-peak variations of a carrier frequency caused by external variations not a part of normal action of the carrier-tuned circuits. 3. In a klystron, frequency modulation of the fundamental frequency due to shot and ion noises, ac heater voltage, etc.

incident field intensity—The field strength of a down-coming sky wave, not including the effects of earth reflections at the receiving location.

incident light—The light that falls directly on an object.

incident-light meter—An exposure meter designed to measure the light striking an object and used at a suitable location in the scene.

incident power—The product of the outgoing current and voltage traveling from a transmitter down a transmission line to an antenna.

incident ray—A ray of light that falls on or strikes a surface of an object, such as a lens. It is said to be incident to the surface.

incident wave—In a medium of certain propagation characteristics, a wave that strikes a gap in the medium or strikes a medium having different propagation characteristics.

incipient failure—A degradation failure in its beginning stages.

in-circuit emulation—Abbreviated ICE. A capability provided on some microcomputer development systems that enables a system designer to use the facilities of the development system to debug prototype hardware and software. This is accomplished via an umbilical cable from the development system that plugs into the microprocessor socket in the prototype system. See also emulation.

in-circuit emulator—Abbreviated ICE. A microcomputer development system that can be plugged into a microcomputer system to control, alter, interrogate, and debug that system using a known good environment.

in-circuit tester—Also called a bed-of-nails tester or an in-situ tester. A tester that checks the individual components on a board using a fixture that provides access to each node of each component. Used to test for short and open circuits on bare boards, correct values of analog components (using a guarding technique), and correct functions of individual ICs (using a pulsing technique).

inclination—1. The angle between the orbital plane of a satellite and the equatorial plane of the earth. 2. The angle that a line, surface, or vector makes with the horizontal.

inclinometer—An instrument for measuring the magnetic inclination of the earth's magnetic field. It uses a magnetic needle that pivots vertically to indicate the inclination.

inclusive AND—A logic element whose output is true if all inputs are true, all inputs are false, or all inputs but one are false.

inclusive NAND—A logic element whose output is true if one and only one of the inputs is false.

incoherent—Denotes the lack of a fixed phase relationship between two waves. If two incoherent waves are superposed, interference effects cannot last longer than the individual coherent times of the waves.

incoherent detection—Detection wherein the information contained in the phase of the carrier is discarded.

incoherent emitter—A fiber-optic source of radiation that has been used for short-length optical transmission lines. Light-emitting diodes are incoherent emitters. See coherent emitter.

incoherent scattering—The disordered change in their direction of propagation that occurs when radio waves encounter matter.

incoherent source—A fiber-optic light source that emits wide, diffuse beams of light of many wavelengths. The light waves emitted from an incoherent source are out of phase. Contrast coherent source.

incoming—Describing a telecommunication trunk that is used only for calls coming in from another office.

incoming selector—In a telephone central office, a selector associated with trunk circuits from another central office.

incomplete sequencer relay—A device that returns the equipment to the normal, or off, position and locks it out if the normal starting, operating, or stopping sequence is not properly completed within a predetermined time.

increductor—A controllable inductor similar to a saturable reactor, except that it is capable of operating at high frequency (e.g., up to 400 MHz).

Increductor.

increment—1. A small change, either positive or negative, in the value of a variable quantity. 2. See step angle.

incremental compiler—In a computer, a compiler capable of compiling additional statements without a complete recompilation.

incremental computer—1. A computer in which the use of incremental representation of data is predominant. 2. A special-purpose computer designed specifically to process changes in the variables as well as absolute values of the variables.

incremental digital-position transducer equalizer—Digital-position transducer that, without absolute position reference, produces a digital signal by motion.

incremental digital recorder—A magnetic tape recorder that advances the tape across the recording head step by step, as in a punched-tape recorder. It is used for economical and reliable recording of an irregular flow of data.

incremental frequency shift—A method by which incremental intelligence may be superimposed on other intelligence by shifting the center frequency of an oscillator a predetermined amount.

incremental hysteresis loss—Losses in a magnetic material that has been subjected to a pulsating magnetizing force.

incremental induction—One-half the algebraic difference between the maximum and minimum magnetic induction at a point in a material that has been subjected simultaneously to a polarizing and a varying magnetizing force.

incremental integrator—A digital integrator modified so that the output signal is maximum negative, zero, or maximum positive when the value of the output is negative, zero, or positive, respectively.

incremental permeability—1. The ratio of the cyclic change in magnetic induction to the corresponding cyclic change in magnetizing force when the mean induction differs from zero. For small changes in magnetizing force, the incremental permeability is approximately equal to the slope of the minor hysteresis loop generated. 2. The ratio of incremental change in flux density to the incremental change in magnetizing force at any point on the hysteresis loop.

incremental sensitivity—The smallest change that can be detected by a particular instrument in a quantity under observation.

incremental tape—Magnetic tape written one character at a time instead of the usual method of continuous recording.

incremental tuner—A television tuner in which antenna, rf amplifier, and rf oscillator inductors are continuous or in small sections connected in series. Rotary switches, connected to taps on the inductors, provide the portion of total inductance required for a channel, or short-circuit all remaining inductance except that required for the channel.

independent failure—A failure that has no significant relationship to other failures in a given device and can occur without interaction with other component parts in the equipment.

independent load contacts—Contacts that can control electrical loads that must be isolated from the timer clutch solenoids and motor circuit.

independent variable—One of several voltages and currents chosen arbitrarily and considered to vary independently.

indeterminacy—The time coincidence uncertainty between an external input trigger pulse and an independently clock-derived output pulse from a timing unit such as a digital delay generator. It stems from a clock pulse versus trigger pulse phase uncertainty and is usually expressed in terms of nanoseconds or microseconds. For

example, the $\pm 1/2$ clock pulse uncertainty of a 10-MHz source would be ± 50 ns.

indeterminate state—The unknown logic state (X) of a memory element caused by critical races or oscillations, or existing after power is applied and before initialization. Some simulators can model indeterminate states and typically assign an X to indicate an indeterminate state.

index counter—An odometer-type cumulative-digit indicator for keeping track of the amount of tape that has passed through a tape machine. The counter is generally driven by the takeup-reel turntable and thus registers rotation rather than tape footage, although the accuracy is generally good enough to allow for locating specific recorded segments according to previously noted index counter numbers.

indexed address—An address that is altered by the content of an index register before or during the execution of a computer instruction.

indexed addressing—1. An addressing mode in which a computer finds the address of the desired memory location by referring to an index register. By successively adding or subtracting 1 to this index register, the computer can be made to step through a list or table. 2. An addressing system in which the address of the data is expressed as relative to the address stored in an index or pointer register. To obtain the absolute address, the offset address is added to the pointer address. This system is useful in processing tables or matrices of data.

index hole—A hole punched in a floppy disk to indicate the beginning of the first sector.

indexing—In a computer, a technique of address modification that is often implemented by means of index registers.

indexing mechanism—A mechanical device on a rotary switch to locate and to maintain each position of the rotor.

indexing slots—*See* polarizing slots.

index matching fluid—In fiber optics, a fluid with a refractive index the same as a fiber core; used to fill the air gap between the fiber ends at connectors.

index matching materials—Materials used in intimate contact between the ends of optical conductors to reduce coupling losses by reducing Fresnel loss.

index of cooperation—In rectilinear scanning or recording, the product of the total length of a line and the number of lines per unit length.

index of modulation—The modulation factor.

index of refraction—1. Ratio of the speeds of light or other radiation in two different materials. This determines the amount the ray will be refracted or bent when passing from one material to the other, such as from air to water. The index of refraction of air is generally taken as unity. 2. The physical property of a material that describes the behavior of optical energy passing through it. It is defined as the ratio of the velocity of light in a vacuum to the velocity of light in the material. It varies with wavelength.

index register—1. In a computer, a register that holds a quantity that may be used for modifying addresses or for other purposes, as directed by the program. 2. In a computer, a register whose contents can be added automatically to an address field contained in an instruction, when the indexing mode is specified. 3. A user-accessible register implicitly used for address computation by many instructions that reference main memory.

indicating demand meter—A meter equipped with a scale over which a pointer is advanced to indicate maximum demand.

indicating fuse—A protective device placed in a telephone circuit to provide visual and audible indication of a fault in the line. It consists of a fuse, pilot lamp, relay, and buzzer. When a line fault blows the fuse, the lamp lights and the buzzer sounds.

indicating instrument—An instrument that visually indicates only the present value of the quantity being measured.

indicating lamp—A lamp that indicates the position of a device or the condition of a circuit.

indicating meter—A meter that gives a visual indication of only the present or short-time average value of the measured quantity.

Indicating meter.

indication—The display to the human senses of information concerning a quantity being measured.

indicator—An instrument that makes information available but does not store it.

indicator gate—A rectangular voltage waveform applied to the grid or cathode circuit of an indicator cathode-ray tube to sensitize or desensitize the tube during the desired portion of the operating cycle.

indicator tube—An electron-beam tube that conveys useful information by the variation in cross section of the beam at a luminescent target.

indirect-acting recording instrument—An instrument in which the marking device is actuated by raising the level of measurement energy of the primary detector. This is done mechanically, electrically, electronically, photoelectrically, or by some other intermediate means.

indirect address—An address in a computer instruction that indicates a location where the address of the referenced operand is to be found.

indirect addressing—1. A method of computer cross reference in which one memory location indicates where the correct address of the main fact can be found. 2. A method of storage addressing in which an addressed location contains an address rather than data. Quite often several levels of indirect addressing may occur before the sought-after data item is obtained.

indirect light—Light from an object that has no self-luminous properties. Instead, it reflects light from another source.

indirect lighting—A system of lighting in which all the light is directed to the ceiling or walls, which in turn reflect it to the objects to be illuminated. Lighting by luminaries distributing 90 to 100 percent of the emitted light upward.

indirectly controlled variable—A variable that is related to and influenced by the directly controlled variable but is not directly measured for control.

indirectly heated cathode—Also called equipotential or unipotential cathode. A cathode that is heated by an independent heater.

indirectly heated thermistor—A thermistor that incorporates, as part of its composite structure, an electrical heater. A thermistor whose body temperature in use is significantly higher than the temperature of its surrounding medium as a result of current passing through its heater.

indirect material—A type of semiconductor material in which electrons do not drop directly from the conduction band to the valence band, but drop in steps as a result of the trapping levels in the forbidden gap.

indirect piezoelectricity—The production of a mechanical strain in a crystal by applying a voltage to it (as opposed to the more common piezoelectric effect of applying a strain to the crystal in order to produce a voltage).

indirect radiative transition—See transition, 1.

indirect scanning—A television technique used in early mechanical systems, and today in the flying-spot scanning of films. A small beam of light is moved across the subject and then reflected to a battery of phototubes.

indirect synthesizer—A synthesizer employing phase-locked loops, digital dividers, and high- Q varactor-tuned oscillators. The discrete output frequencies are not limited to integer ratios of the reference frequency. Frequency step size or increments are primarily determined by the digital dividers. Switching speed between discrete output frequencies is usually limited by the phase-lock circuits. Applications include automatic test and satellite communications systems.

indirect wave—A wave reaching a given reception point by a path from the transmitting point other than the direct-line path between the two (e.g., a sky wave received after deflection from the ionosphere layers).

individual gap azimuth—In a magnetic-tape record or reproduce head stack, the angle of an individual gap relative to a line perpendicular to the precision-milled mounting pads in a plane parallel to the surface of the tape.

individual line—A subscriber line that serves one main station and optional additional stations connected to the line as extensions; the line is not arranged for discriminatory ringing with respect to the stations.

indoor antenna—Any receiving antenna located inside a building but outside the receiver.

indoor transformer—A transformer that must be protected from the weather.

Indox—The trade name of Indiana Steel Products Company's barium ferrite permanent magnet alloy.

induced—Produced by the influence of an electric or magnetic field.

induced charge—1. An electrostatic charge produced in one object by the electric field surrounding a nearby object. 2. An electrostatic charge produced on a conducting body when it is brought near to or connected to another body that bears an electric charge.

induced current—1. The current that flows in a conductor that is moved perpendicularly to a magnetic field, or which is subjected to a magnetic field of varying intensity. The former takes place in an induction-motor rotor; the latter, in the secondary winding of a transformer. 2. In induction heating, the current that flows in a conductor when a varying electromagnetic field is applied. 3. The current that results when a conductor is cut by magnetic flux lines. 4. Current that flows in a conductor because of an induced voltage.

induced electromotive force—Represented by E ; proportional to the rate of change of magnetic flux through the circuit ($d\phi/dt$).

induced environment—The temperatures, vibrations, shocks, accelerations, pressures, and other conditions

imposed on a system due to the operation or handling of the system.

induced failure—A failure that is basically caused by a condition or phenomenon external to the item that fails.

induced voltage—The voltage produced in a conductor when the conductor is moved up and down through the magnetic field of a second conductor, or when the field varies in intensity and cuts across the first conductor. Even though there is no mechanical coupling between the two conductors, the one producing the field will produce a voltage in the other.

inductance—1. Property of a circuit that tends to oppose any change of current because of a magnetic field associated with the current itself. Whenever an electric current changes in value—rises or falls—in a circuit, its associated magnetic field changes, and when this links with the conductor itself, an electromotive force is induced that tends to oppose the original current change. Self-inductance is the full name for this, but the term *inductance* is usually used. The unit of inductance is the henry. When a current changing at the rate of 1 ampere per second induces a voltage of 1 volt, the inductance of the circuit is 1 henry. 2. *See also* coil. 3. The property of a circuit or circuit element that opposes a change in current flow, thus causing current changes to lag behind voltage changes. It is measured in henrys.

inductance bridge—An instrument, similar to a Wheatstone bridge, for measuring an unknown inductance by comparing it with a known inductance.

inductance coil—*See* inductor.

inductance-tube modulation—A method of modulation employed in frequency-modulated transmitters. An oscillator control tube acts as a variable inductance in parallel with the tank circuit of the radio-frequency oscillator tube. As a result, the oscillator frequency varies in step with the audio-frequency voltage applied to the grid of the oscillator control tube.

induction—1. The establishment of an electric charge or a magnetic field in a substance by the proximity of an electrified source, a magnet, or a magnetic field. 2. The setup of an electromotive force and current in a conductor by variation of the magnetic field affecting the conductor.

induction brazing—The electric brazing process in which heat is produced by an induced current.

induction coil—A device for changing direct current into high-voltage alternating current. Its primary coil contains relatively few turns of heavy wire; its secondary coil, wound over the primary, contains many turns of fine wire. Interruption of the direct current in the primary by a vibrating-contact arrangement induces a high voltage in the secondary.

induction compass—A compass in which the indications are produced by the current generated in a coil revolving in the magnetic field of the earth.

induction-conduction heater—A heating device through which electric current is conducted but is restricted by induction to a preferred path.

induction density—*See* flux density.

induction factor—In an alternating-current circuit, the ratio between that element of the current that does no work and the total strength of the current.

induction field—1. That portion of the electromagnetic field of a transmitting antenna that acts as if it were permanently associated with the antenna, and into which energy is alternately stored and removed. 2. The electromagnetic field of a coil carrying alternating current, responsible for the voltage induced by that coil in itself or in a nearby coil. 3. The magnetic field that is predominant

in the near zone of a radio transmitting antenna and that is directly proportional to the current in the antenna.

induction frequency converter—A slip-ring induction machine driven by an external source of mechanical power. Its primary circuits are connected to a source of electric energy having a fixed frequency. The energy delivered by its secondary circuits is proportionate in frequency to the relative speed of the primary magnetic field and the secondary member.

induction furnace—A furnace heated by electromagnetic induction.

induction hardening—The process of hardening the surface of a casting by heating it above the transformation range by electrical induction, followed by rapid cooling.

induction heating—The method of producing heat by subjecting a material to a variable electromagnetic field. Internal losses in the material then cause it to heat up.

induction instrument—An instrument operated by the reaction between the magnetic flux set up by one or more currents in fixed windings and the currents set up by electromagnetic induction in movable conductive parts.

induction loudspeaker—A speaker in which the current that reacts with the steady magnetic field is induced in the moving member.

induction motor—1. An alternating-current motor in which the primary winding (usually the stator) is connected to the power source and induces a current into a polyphase secondary or squirrel-cage secondary winding (usually the rotor). Currents, and therefore magnetic poles, are induced into the secondary by the rotating primary magnetic field; thus, the armature rotates at slightly slower than synchronous speed, a condition that is called slip. The amount of slip increases with an increase in mechanical loading. 2. A motor that runs asynchronously; that is, not in step with the alternations of the alternating current.

induction-motor meter—A meter containing a rotor that moves in reaction to a magnetic field and the currents induced into it.

induction noise—The noise—other than thump, flutter, cross fire, or crosstalk—produced when two circuits are inductively coupled together.

induction-resistance welding—Welding in which electromagnetic induction alone causes the heating current to flow in the parts being welded.

induction-ring heater—A core-type induction heater adapted principally for heating round objects. The core is open or can be taken off to facilitate linking the charge.

induction soldering—A method of soldering in which the solder is reflowed or supplied by preforms. If the work is moved slowly through the energy field, the induction process may be made continuous.

induction speaker—A speaker in which the current that reacts with the steady magnetic field is induced into the moving member.

induction-voltage regulator—A device having a primary winding in shunt and a secondary winding in series with a circuit for gradually adjusting the voltage or the phase relation of the circuit by changing the relative positions of the exciting and series windings of the regulator.

inductive—Pertaining to inductance or to the inducing of a voltage through mutual or electrostatic induction.

inductive circuit—A circuit with more inductive than capacitive reactance. A circuit having a net inductive reactance; that is, a higher value of inductance reactance than of capacitive reactance.

inductive coordination—Location, design, construction, operation, and maintenance of electric supply and communication systems in a manner that prevents inductive interference.

inductive coupled circuit—A network with two meshes having only mutual inductance in common.

inductive coupling—1. The association of one circuit with another through inductance common to both. When used without modifying words, the term commonly refers to coupling by means of mutual inductance, whereas coupling by means of self-inductance common to both circuits is called direct inductive coupling. 2. In inductive-coordination practice, the interrelation of neighboring electric supply and communication circuits resulting from electric and/or magnetic induction. 3. Coupling that exists between two circuits through a mutual inductance, such as that in a transformer. 4. Coupling between two circuits through an inductance that is common to the two circuits; direct inductive coupling.

inductive feedback—The transfer of energy from the output circuit to the input circuit of an amplifying device through an inductor or inductive coupling.

inductive interference—1. Interference produced in communication systems by induced voltages within the system. 2. Effect arising from the characteristics and inductive relations of electric supply and communication systems of such character and magnitude as would prevent the communication circuit from rendering service satisfactorily and economically if methods of inductive coordination were not applied.

inductive kick—1. The voltage, many times higher than the impressed voltage, produced by the collapsing field in a coil when the current through it is abruptly cut off. 2. A voltage surge that is induced in an inductance when the current through it is interrupted and the magnetic flux collapses suddenly.

inductive level detector—A level-measuring system incorporating an oscillator and electromagnetic field.

inductive load—Also called lagging load. A load that is predominantly inductive, so that the alternating load current lags behind the alternating voltage of the load. An electrical load that has a significant inductive reactance.

inductive microphone—*See* inductor microphone.

inductive neutralization—Also called shunt or coil neutralization. A method of neutralizing an amplifier, whereby the equal and opposite susceptance of an inductor cancels the feedback susceptance caused by interelement capacitance.

inductive pickup—Signals generated in a circuit or conductor due to mutual inductance between it and a disturbing source.

inductive post—A metal post or screw extended across a waveguide parallel to the E field to act as inductive susceptance in parallel with the waveguide for purposes of tuning or matching.

inductive reactance—The opposition to the flow of alternating or pulsating current by the inductance of a circuit. It is measured in ohms, and its symbol is X_L . It is equal to 2π times the frequency in hertz times the inductance in henrys.

inductive system—An ignition system that stores its primary energy in an inductor or coil.

inductive transducer—A transducer in which changes in inductance convey the stimulus information.

inductive transduction—The conversion of the measurand into a change in the self-inductance of a single coil.

inductive tuning—A method of tuning a radio by moving a core into and out of a coil to vary the inductance.

inductive coordination — industrial television

inductive winding—A coil through which a varying current is sent to give it an inductance.

inductive window—A conducting diaphragm extended into a waveguide from one or both sidewalls to act as an inductive susceptance in parallel with the waveguide.

inductometer—An inductor whose inductance can be varied, sometimes by a calibrated amount.

inductor—Also called inductance or retardation coil.

1. A conductor used for introducing inductance into an electric circuit. The conductor is wound into a spiral, or coil, to increase its inductive intensity. 2. A passive fluidic element that, because of fluid inertness, has a pressure drop that leads flow by essentially 90° . 3. *See* coil.

TOROID

SOLENOID

Inductors.

inductor microphone—Also called inductive microphone. A microphone in which the sound waves move a conductor back and forth, cutting magnetic lines of force and producing an electrical output of the same frequency and proportional to the amplitude of the sound waves.

inductor-type synchronous motor—A type of synchronous motor having field magnets that are fixed in magnetic position relative to the armature conductors, the torques being produced by forces between the stationary poles and salient rotor teeth. Such motors usually have permanent-magnet field excitation, are built in fractional-horsepower frames, and operate at low speeds (300 revolutions per minute or less).

Inductosyn—An extremely precise transducer based on the magnetic circuit of a conductor deposited on glass for stability, and operated at a relatively high frequency. Extremely accurate, but requires much auxiliary equipment (Farand Controls Inc.).

industrial-grade IC—Typically, an integrated circuit whose performance is guaranteed over the temperature range 0 to 70°C .

industrial radio services—Radiocommunication services essential to, operated by, and for the sole use of those enterprises that require radiocommunications in order to function efficiently.

industrial television—The cameras and related instrumentation of a closed-circuit television system. Such equipment is designed to function in the different environments found in industrial processes. Used to monitor areas that are hazardous to personnel, such as high-radiation

areas, areas that do not require steady supervision, industrial processes for surveillance or quality control, or areas requiring security measures.

industrial timer—A timing device, impulse or constant-speed type, used in industrial applications other than the appliance industry.

industrial tube—A vacuum tube designed for industrial electronic equipment.

inelastic collision—Collision resulting in excitation of a molecule.

inertance—Acoustical equivalent of inductance.

inert gas—See noble gas.

inertia—1. The tendency of an object at rest to remain at rest, or of a moving object to continue moving in the same direction and at the same speed, unless disturbed by an outside force. Resulting from mass and inhibiting change in velocity. Important in pickup mechanics. 2. The resistance to change in speed or velocity. In stepper motors, inertia does not affect the maximum stepping rate, only the time required to attain it.

inertial guidance/navigation—A self-contained system for navigation in which position can be computed by knowing a craft's starting point and where it has been. Changes in acceleration are detected by gyroscopes for direction and attitude and by accelerometers for velocity. These signals are integrated to determine resulting velocity and distance. The system needs no outside reference and cannot be jammed.

inertial navigation—1. A guidance technique in which airframe acceleration is first measured and then integrated twice with respect to time in order to determine the distance traveled. External aids such as radio and radar are not necessary. The acceleration or deceleration of the airframe is measured continuously with accelerometers oriented in some convenient frame of reference, usually corresponding to the earth's north-south, east-west coordinates. 2. A form of navigation that uses dynamic measurements of acceleration forces acting on a gyroscopically stabilized device as a basis for computing position and velocity information. This device, which is mechanized so as to be completely self-contained, has the inherent capability of providing continuously available navigation information in terms of conventional, directly usable latitude and longitude coordinates.

inertia relay—A relay having added weights or other modifications that increase its moment of inertia and either slow it or cause it to continue in motion after the energizing force is removed.

inertia switch—A switch capable of sensing acceleration, shock, or vibration. It is designed to actuate upon an abrupt change in velocity.

inertia welding—A forge-welding process in which stored kinetic energy is released as frictional heat when two parts are rubbed together under the proper conditions.

infant mortality—The occurrence of premature catastrophic-type failures of a component or equipment

at a rate substantially greater than that observed during life prior to wearout.

infant-mortality period—See early-failure period.

inferential—The kind of instrumentation, especially its signal source, in which there is sampling of an entirely different quantity from the one of interest, upon the assumption that they vary in perfect proportion. Linearity or a perfectly repeatable relationship between the two is inferred for the sake of a more convenient signal-source arrangement.

infiltration—The process of filling the pores of a sintered compact with a metal or alloy of lower melting point.

infinite—Boundless; having no limits whatsoever.

infinite baffle—1. An airtight speaker enclosure that completely absorbs or dissipates a speaker's rear sound waves. 2. A speaker mounting in which ideally there is no path of air between the back and front of the speaker diaphragm. An infinite baffle improves the forward radiation of sound at low frequencies and preferably should be a very large plane surface, like the wall of a room or a screen of very rigid material (e.g., 3/4-inch or 2-cm wood), on which a speaker is mounted. (In practice, truly infinite baffles are rarely accomplished except in sealed boxes, but these give rise to problems of resonance.) 3. An airtight speaker enclosure containing a bass speaker with very low open-air resonance, plus a sealed midrange speaker and tweeter.

infinite-baffle speaker system—A speaker in which the bass driver is located in an almost airtight enclosure.

infinite-impedance detector—A detector circuit in which the load is a resistor connected in parallel with an rf bypass capacitor between the cathode and ground. Since the grid is always negative with respect to the cathode, the tube presents an infinite impedance to the input.

infinite line—A transmission line with the same characteristics as an ordinary line that is infinitely long.

infinite resolution—The capability of a device to provide continuous output over its entire range.

infinitesimal—Immeasurably small; approaching zero.

infinity—1. A hypothetical amount larger than any assignable amount. 2. A number larger than any number a computer can store in any register. 3. Any distance of a subject from a lens for which the image no longer moves when the subject moves along the optical axis.

infinity device—Also called harmonica bug. A surreptitious listening device that uses the telephone as a sensor. Allows the bugger to listen to sounds near the phone while the phone is not in use. Does not allow him or her to hear telephone conversations.

inflection point—The point at which a curve changes direction.

infobond—An automated system of point-to-point wiring on the back of a two-sided printed wiring board (the components are on the front, or other side). The No. 38 AWG copper wire used is solder-bonded to terminations by an automatic soldering gun.

information—1. In computing, the basic data and/or program entered into the system. 2. That property of a signal or message whereby it conveys something meaningful and unpredictable to the recipient, usually measured in bits. 3. Data that has been organized into a meaningful sequence.

information bits—In telecommunications, those bits originated by the data source and not used for error control by the data-transmission system.

information center—A facility specifically designed for storing, processing, and retrieving information

Infant mortality.

to be disseminated at regular intervals, on demand, or selectively, according to the needs of users.

information channel—The transmission and intervening equipment involved in the transfer of information in a given direction between two terminals. An information channel includes the modulator and demodulator and any error-control equipment irrespective of its location, as well as the backward channel, when provided.

information extraction—An analysis of an image to recognize and isolate a specific feature or relationship among features.

information feedback system—In telecommunications, an information-transmission system in which an echo check is employed to verify the accuracy of the transmission.

information gate—A circuit that permits information or data pulses to pass when the circuit is triggered by an external source.

information handling—The storing and processing of information and its transmission from the source to the user. Information handling excludes the creation and use of information.

information processing—A term that encompasses both word processing and data processing. It describes the entire scope of operations performed by a computer.

information rate—In computers, the minimum number of binary digits per second required to specify the source messages.

information rate changer—A device that speeds up the playback of tape-recorded speech without pitch change or deterioration of characteristic resonances. This is accomplished by rotating the playback head in the direction of tape travel.

information retrieval—1. A method for cataloging vast amounts of data related to one field of interest so that any part or all of this data can be called out at any time with accuracy and speed. 2. The recovery of data that has been stored at a particular address in a memory. 3. A technique of classifying and indexing useful data in mass storage devices in a format amenable to interaction with the user(s). 4. The art of storing information so that it may be recovered easily. Branches include abstracting, locating facts of interest, and language translation.

information-retrieval system—A system for locating and selecting on demand certain documents or other graphic records relevant to a given information requirement from a file of such material.

information separator—A control character used to identify a logical boundary of information. The name of the separator is not necessarily indicative of what it separates.

information superhighway—The concept of a high-bandwidth network that links everyone with everyone and can transport all media types. The information superhighway links the concepts of online services, Internet, and interactive TV together.

information system—A group of computer-based systems and data required to support the information needs of one or more business processes.

information theory—1. The branch of learning that deals with the likelihood of accurate transmission of messages subject to transmission failure, distortion, and noise. 2. The mathematical theory that deals with the transmission of information and the effects of bandwidth, distortion, and noise.

infra—Prefix meaning below; beneath; less than.

infra-dyne receiver—A superheterodyne receiver whose intermediate frequency is made higher than the signal frequency in order to obtain high selectivity.

infrared—Abbreviated IR. 1. Pertaining to or designating those radiations with wavelengths just beyond the red end of the visible spectrum, such as those emitted by a hot body. These wavelengths are longer than those of visible light and shorter than those of radio waves. 2. That section of the electromagnetic spectrum, invisible to the eye, lying between wavelengths of 750 nm and about 1 mm. Thermography utilizes waves in this region for recording changes in temperature. 3. Part of the electromagnetic spectrum between the visible light range and the radar range. 4. The electromagnetic wavelength region between approximately 0.75 and 1000 micrometers. For fiber-optic transmission, the near-infrared region between 0.75 and 1.3 micrometers is the most relevant region because glass, light sources, and detector techniques are most nearly matched in this wavelength region.

infrared alarm systems—A system that uses infrared detectors and related instrumentation to determine when abnormal amounts of infrared radiation, usually in the form of heat, are present in an area; used for the detection of fires or the presence of intruders in a restricted area.

infrared binoculars—An instrument, similar in design to regular binoculars, that can transmit and enlarge infrared images using electronic circuits.

infrared communications set—The collection of components necessary to operate a two-way electronic system in which infrared radiation is used to carry intelligence.

infrared counter-countermeasures—Action taken to employ infrared radiation equipment and systems in spite of enemy measures to counter their use.

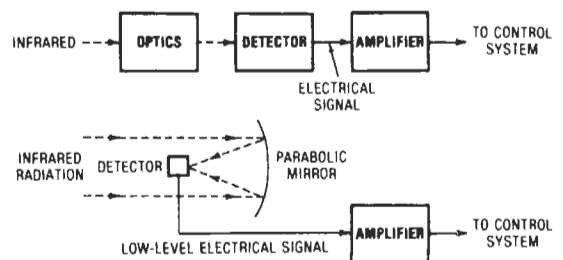

infrared countermeasures—Action taken to reduce the effectiveness of enemy equipment employing infrared radiation.

infrared detector—A transducer that is sensitive to invisible infrared radiation (wavelengths between 0.75 and 1000 micrometers), usually using a semiconductor (photon), thermocouple bolometer, or pneumatic (pressure) device to detect the radiation. Also a device used to detect radiation from the infrared region.

infrared emitter—See infrared light-emitting diode.

infrared-emitting diode—1. A semiconductor device with a semiconductor junction in which infrared radiant flux is nonthermally produced when a current flows as a result of applied voltage. 2. A pn diode in which a fraction of the injected minority carriers recombine by means of radiative transitions. When the junction is forward biased, electrons from the n region are injected into the p region, where they recombine with excess holes. In the radiative process, energy given up in recombination is in the form of photon emission. The generated photons travel through the lattice until they are either reabsorbed by the crystal or escape from the surface as radiant flux.

infrared guidance—A system using infrared heat resources for reconnaissance of targets or for navigation.

Infrared guidance.

infrared homing—A type of missile homing in which the guidance system tracks the target from the infrared radiation it emits. *See* heatseeker.

infrared instruments—Any of the photoelectric and thermal detectors, spectrographs and monochromators, thermographs, scanners, amplifier tubes, snooperscopes, and related equipment especially developed for use with infrared radiation.

infrared jamming—A countermeasure used against heatseeking missiles to reduce their effectiveness. Normally it involves the emittance of infrared radiation at a level that will overload the missiles' detectors.

infrared light—Light rays just below the red end of the visible spectrum.

infrared light-emitting diode—Also called infrared emitter. An optoelectronic device containing a semiconductor pn junction that emits radiant energy in the 0.75- to 100-micrometer wavelength region when forward biased.

infrared motion detector—A sensor that detects changes in the infrared light radiation from parts of the protected area. Presence of an intruder in the area changes the infrared light intensity from his or her direction.

infrared optics—Lenses, prisms, and other optical elements for use with infrared radiation (radiation with a wavelength between 0.75 and 1000 micrometers).

infrared ovens—Units that dry, cure, and preheat parts directly (i.e., without heating the oven air) via infrared energy.

infrared radiation—1. Invisible radiation with wavelengths in the range between 7500 angstroms (red) and about 1,000,000 angstroms (microwaves). 2. The electromagnetic wavelength region between approximately 0.75 and 1000 micrometers, longer than the wavelength of visible light.

infrared radiation sources—Almost any warm thing, from an electric blanket to a living human being, that acts as a source for the longer wavelength end of the IR range, which generally is regarded as extending from 0.75 to 1000 micrometers. Calibrated secondary sources are usually a heated cavity (blackbody) or a carbon filament lamp rated in wattage output or in ergs per second of radiation incident on a surface at a specified distance.

infrared sources—Emitters of radiation with a wavelength between 0.75 and 1000 micrometers.

infrared spectrum—That portion of the electromagnetic spectrum between the wavelengths of 0.75 and 1000 micrometers.

infrared thermometer—A temperature-measuring device that detects infrared radiation from an object and converts that measurement into a reading representing the temperature of the object.

infrared waves—Also called black light. Invisible waves longer than the longest visible red light waves but shorter than radio-frequency waves.

infrared window—A region of relatively high transmission in the infrared-frequency range.

infrasonic—Pertaining to frequencies below the range of human hearing, hence below about 15 hertz. Formerly called subsonic.

infrasonic frequency—A frequency below the audio range. Infrasonic vibrations can be felt but not heard. Replaces the obsolete term *subsonic frequency*.

inharmonic frequency—A frequency that is not a rational multiple of another frequency.

inherent delay—Delay between the insertion of information into a unit and presentation of the information at the output. For example, a delay inserted into the CRT vertical amplifier of pulse analyzers to allow the leading

Infrared spectrum.

edge of the signal triggering the sweep to be seen. *See* also insertion delay.

inherent interference—A type of electromagnetic interference generated within a receiver by thermal agitation, shot effect, and nonlinear impedance.

inherent reliability—The potential reliability of an item present in its design.

inherited error—In a computer, the error in the initial values, especially that error accumulated from prior steps in a step-by-step integration.

inhibit—To prevent an action from taking place or data from being accepted by applying an appropriate signal (generally a logic 0 in positive logic) to the proper input.

inhibit gate—A circuit that provides an output only when certain signals are present and other signals are not present at the inputs.

inhibiting input—A computer gate input which, in its prescribed state, prevents any output which might otherwise occur.

inhibiting signal—A signal whose presence prevents an operation from taking place.

inhibition gate—A gate circuit used as a switch and placed in parallel with the circuit it is controlling.

inhibitor—Also called inhibition gate. In a digital computer, a logic circuit that clamps a specified output to the zero level when energized.

inhibit pulse—A computer drive pulse that tends to prevent certain drive pulses from reversing the flux of a magnetic cell.

initial actuation time—The time of the first closing of a previously open contact of a relay or the first opening of a previously closed contact.

initial contact chatter—That chatter caused by vibration produced by opening or closing the contacts in a relay themselves, as by contact impact in closure.

initial differential capacitance—The differential capacitance of a nonlinear capacitor when the capacitor voltage is zero.

initial drain—The current supplied at nominal voltage by a cell or battery.

initial element—See primary detector.

initial erection—The mode of operation of a vertical gyro in which the gyro is being erected or slaved initially. The initial erection rate is usually relatively fast.

initial failure—The first failure that occurs in use.

initial inverse voltage—Of a rectifier tube, the peak inverse anode voltage immediately following the conducting period.

initial ionizing event—Also called primary ionizing event. An ionizing event that initiates a tube count.

initialization—1. The process in which information (memory locations for data and results, tolerances, limits, etc.) is supplied to a computer prior to the running of a program. 2. Applying input patterns to a logic circuit so that all internal memory elements achieve a known logic state. 3. A process that takes place whenever the state of a device or program must be known at startup.

initialize—1. To set counters, switches, and addresses to their starting values at the beginning of a computer routine or at prescribed points in the routine. 2. To establish an initial condition or starting state; for example, to set logic elements in a digital circuit or the contents of a storage location to a known state so that subsequent application of digital test patterns will drive the logic elements to another known state. 3. To reset a computer and its peripherals to a starting state before beginning a task. Done automatically by the disk operating system.

initializing—1. The preliminary steps in arranging those instructions and data in a computer memory that are not to be repeated. 2. Setting flip-flops to known states prior to testing.

initial permeability—The slope of the normal induction curve at zero magnetizing force. Permeability at a field density approaching zero.

initial program loader—The procedure that results in loading of the initial part of an operating system or other program so that the program can then proceed under its own control.

initial reversible capacitance—In a nonlinear capacitor, the reversible capacitance at a constant bias voltage of zero.

initial-velocity current—A current that flows between an electrode, such as the grid of a vacuum tube, and its cathode as a result of electrons thrown off from the cathode because of heat alone. Their velocity is sufficient to allow the electrons to reach the grid unaided by an accelerating field.

injected laser—See diode laser.

injection grid—A vacuum-tube grid that controls the electron stream without causing interaction between the screen and control grids. In some superheterodyne receivers, the injection grid introduces the oscillator signal into the mixer stage.

injection laser—Also known as a pn junction laser. 1. An optical oscillator or amplifier that has as its active medium a forward-biased semiconductor diode in which a population inversion has been established between the conduction and valence bands. Radiation is emitted in the process of recombination across the bandgap. High frequency modulation of the output beam can be achieved by modulating the input current. Usually, the optical resonator is formed by cleaving or polishing opposite faces of the diode crystal. Typical dimensions of the device are 0.1 mm × 0.1 mm × 0.5 mm. 2. A semiconductor diode carrying a high current in the forward direction. Radiation is produced as electrons recombine with holes in the

initial differential capacitance — ink blending

junction region. For coherent emission, the current density must exceed a threshold commonly about 10,000 A/cm² for gallium arsenide diodes. 3. A solid-state semiconductor device with at least one pn junction capable of emitting coherent or stimulated radiation under specified conditions. Incorporates a resonant optical cavity. 4. A solid-state laser having at least one pn junction. Its energy level transitions are between energy bands of semiconductors and it can be tuned in frequency by temperature or pressure alterations and by the effect of a magnetic field.

injection laser diode—1. A coherent radiant source LED consisting of an extremely flat junction area, end mirrors, and direct bandgap semiconductors, having a Fabry-Perot optical cavity. 2. In fiber optics, a semiconductor device in which lasing takes place within the pn junction. Light is emitted from the diode edge.

Injection laser diode.

injection-locked oscillator—Abbreviated ILO. A free-running microwave oscillator that is stabilized by injecting a reference signal into the oscillator's resonant circuitry. The required injected signal level is determined by the output signal characteristic requirements (i.e., noise, stability, etc.) and is typically in the range of 70 to 30 dB below the output level of the ILO.

injection luminescent diode—1. A gallium arsenide diode, operating in either the laser or noncoherent mode, that can be used as a source of visible or near infrared light for use in triggering such devices as light-activated switches. 2. A semiconductor (gallium arsenide) diode operating in either a coherent or incoherent mode that is used as a near-infrared or visible source in triggering light-activated devices.

injector—An electrode on a spaciator.

ink—1. One of several conductive materials used for chip bonding, electrostatic shielding, corona shielding, making connections, repairing on printed circuits, attaching leads, adhesive work, ignition cable sheath coating, and making electrodes, contacts, terminations, and surfaces receptive to plating, etc. 2. Synonymous with *composition* and *paste* when relating to screenable thick-film materials, usually consisting of glass frit, metals, metal oxide, and solvents. 3. In hybrid technology, the conductive paste used on thick-film materials to form the printed conductor pattern. Usually contains metals, metal oxide, glass frit, and solvent. 4. In thick film, composition of micrometer-size polycrystalline solids suspended in a thixotropic vehicle. The solids are chosen for their electrical characteristics (i.e., metals for conductives, metals and oxides for resistives, and glasses for glazes and dielectrics).

ink blending—See blending.

ink-jet printer—A nonimpact printer that forms letters and numbers by electrostatically aiming a jet of ink onto the paper.

Ink-jet printer.

ink-jet printing—A nonimpact printing technique that utilizes droplets of ink to form copy images. As the print head moves across the surface of the copy paper, it shoots a stream of tiny, electrostatically charged ink drops at the page, placing them precisely to form individual print characters.

ink-mist recording—Also called ink-vapor recording. In facsimile, electromechanical recording in which particles of an ink mist are deposited directly onto the record sheet.

ink recorder—The ink-filled pen or capillary tube that produces a graphic record.

ink recording—A type of mechanical facsimile recording in which an inked helix marks the record sheet.

ink-vapor recording—See ink-mist recording.

inleads—Those portions of the electrodes of a device that pass through an envelope or housing.

in-line heads—See stacked heads.

in-line procedures—1. In COBOL, the procedural instructions that are part of the main sequential and controlling flow of the program. 2. Short functions whose code is inserted by the compiler at the point of call, thereby avoiding the overhead of a normal function call.

in-line processing—The processing of data in random sequence not subject to preliminary sorting or editing.

in-line subroutine—A subroutine that is inserted directly into the linear operational sequence. Such a subroutine must be recopied at each point in a routine where it is needed.

in-line tuning—The method of tuning the intermediate-frequency strip of a superheterodyne receiver in which all the intermediate-frequency amplifier stages are made resonant to the same frequency.

inorganic electrolyte—A solution that conducts electricity due to the presence of ions of substances not of organic origin.

in phase—Two waves of the same frequency that pass through their maximum and minimum values of like polarity at the same instant are said to be in phase.

in-phase portion of the chrominance signal—That portion of the chrominance signal having the same phase as, or exactly the opposite phase from, that of the

subcarrier modulated by the I signal. This portion of the chrominance signal may lead or lag the quadrature portion by 90 electrical degrees.

input—1. The current, voltage, power or other driving force applied to a circuit or device. 2. The terminals or other places where current, voltage, power, or driving force may be applied to a circuit or device. 3. Data to be processed. 4. The process of transferring data from an external computer storage to an internal storage. 5. The terminals, jack, or receptacle provided for the introduction of an electrical signal or electric power into a device or system.

input admittance—1. The reciprocal of the input impedance. 2. The admittance between the input terminals with the outputs shorted together.

input area—In a computer, the area of internal storage into which data from external storage is transferred.

input bias current—1. The current that must be supplied to each input of an IC operational amplifier to assure proper biasing of the differential-input-stage transistors. In specification sheets, this term refers to the average of the two input bias currents. 2. One-half the sum of the separate currents entering the two input terminals of a balanced amplifier. 3. The average of the two input currents of an operational amplifier.

input block—In a computer, a section of the internal storage reserved for receiving and processing input data.

input capacitance—1. The capacitance at the input terminals of a device. 2. The capacitance between gate and source terminals of a field-effect transistor at specified bias and frequency conditions, with the drain ac short-circuited to the source.

input channel—A channel through which a state is impressed on a device or logic element.

input common-mode range—The maximum input that can be applied to either input of an operational amplifier without causing damage or abnormal operation.

input common-mode rejection ratio—1. The ratio of the change in input voltage to the corresponding change in output voltage, divided by the open-loop voltage gain. 2. The ratio of the full differential voltage gain to the common-mode voltage gain.

input common-mode voltage range—The range of voltages on the input terminals of an operational amplifier for which the amplifier is operational. Note that the specifications are not guaranteed over the full common-mode voltage range unless specifically stated.

input device—1. The device or set of devices through which data is brought into another device. 2. A device such as a card reader or terminal keyboard that converts data from the form in which it has been received into electronic signals that can be interpreted by the computer.

input equipment—The equipment that introduces information into a computer.

input error voltage—The error voltage appearing across the input terminals of an operational amplifier when a feedback loop is applied around the amplifier.

input extender—A high-speed diode array used in a logic circuit when increased fan-in capability is required.

input formatting—The technique a system uses to put all entered data into a standard (or intelligible) format.

input gap—Also called buncher gap. In a microwave tube, the gap where the initial velocity modulation of the electron stream occurs.

input impedance—1. The impedance a transducer presents to a source. 2. The effective impedance seen looking into the input terminals of an amplifier; circuit details, signal level, and frequency must be specified. 3. The impedance that exists between the input terminals

of an amplifier or transmission line when the source is disconnected.

input impedance of a transmission line—The impedance between the input terminals with the generator disconnected.

input offset current—The difference between the input bias currents flowing into each input of an IC operational amplifier, when the output of the operational amplifier is at zero volts.

input offset voltage—That voltage which must be applied between the input terminals of an operational amplifier, through two equal resistances, to obtain zero output voltage.

input/output—Abbreviated I/O. 1. Pertaining to devices that accept data for transmission to a computer system (input) or that accept data from a computer system for transmission to a user or process. Devices that perform both functions are known as I/O devices (e.g., terminals). 2. A general term for the peripheral devices used to communicate with a digital computer, and the data involved in the communication. 3. The process of transmitting information from an external source to an equipment unit, or from an equipment unit to an external source. 4. Transferring information from an input to an accumulator, or from an accumulator to an output. 5. Interface circuits or devices offering access between external circuits and the central processing unit or memory.

input-output bound—See input-output limited.

input/output connector—A mating pair of connectors used to carry signals into and out of a panel-mounted subsystem. An example is a connector pair that interconnects the individual back panels in a large array of panels.

input-output limited—Also called input-output bound. Pertaining to a system or condition in which the time taken by input and output operations exceeds the time for other operations.

input pins—The terminals of the device to which input logic signals may be applied.

input-power rating—Also called coil rating. A statement of the allowable voltage, current, or power to the actuating element of a relay beyond which unsatisfactory performances will occur.

input process—1. The process in which a device receives data. 2. The transmission of data from peripheral equipment or external storage to internal storage.

input recorder—Any device that makes a record of an input electrical signal.

input reflected current—In dc-dc converters, the peak-to-peak ac current generated by the switching transients. The value of this current should not exceed 1 percent of the nominal input current.

input reflected ripple—A dc-dc converter term that describes the voltage spike resulting from switching generated transient currents as measured at the dc input source.

input register—In a computer, the register of internal storage able to accept information from outside the computer at one speed and supply the information to the computer calculating unit at another, usually much greater, speed.

input resistance—Also called differential input resistance. The small signal resistance measured between the inverting and noninverting inputs of an operational amplifier. Input capacitance is the capacitance seen between the same two inputs.

input resonator—The buncher resonator in a velocity-modulated tube. It modifies the velocity of the electrons in the beam.

input sensitivity—The input signal level that will result in rated output of a piece of amplifying equipment. In preamplifiers, it is the signal that gives the rated voltage output of the preamplifier; in power amplifiers, the signal that gives the rated power output. (In preamplifiers, the phono sensitivity is commonly 1 millivolt; high-level inputs, such as tape and tuner, are commonly 250 millivolts. In power amplifiers, common values are between 0.5 and 1.0 volt.)

input transformer—A transformer that transfers energy from an alternating-voltage source to the input of a circuit or device. It usually provides the correct impedance match as well.

input uncertainty—In an operational amplifier, the algebraic sum of all the factors, including environmental and time effects, that contribute to the nonideal behavior of the input circuit.

input unit—In a computer, the unit that takes information from outside the computer into the computer.

input voltage drift—The change in output voltage of an operational amplifier divided by the open-loop gain, the quotient expressed as a function of temperature or time.

input voltage offset—The dc potential difference between the two inputs of a differential amplifier when the potential difference between the output terminals is zero.

input winding—See signal winding.

inquiry—1. The withdrawal of stored information from an electronic data processing system by interrogating the contents of the storage of a computer. 2. A technique for initiating the interrogation of the contents of the storage of a computer.

inquiry station—A remote terminal from which an inquiry may be sent over a wire line to a computer.

inquiry unit—A device used to extract a quick reply to a random question regarding information in a computer storage.

inrush—The initial surge of current through a load when power is first applied. Lamp loads, inductive motors, solenoids, contactors, valves, and capacitive load types all have inrush or surge currents higher than the normal running or steady-state currents. Resistive loads, such as heater elements, have no inrush.

inrush current—1. The current in a load circuit immediately following turn-on. In capacitive and tungsten-lamp loads, this exceeds steady-state current for some period following turn-on. 2. In a solenoid or coil, the steady-state current drawn from the line with the armature in its maximum open position.

inrush current limiting—Protective circuit in a power supply that prevents excessively large currents through a rectifier to charge the filter capacitors. To prevent unnecessary power loss, the circuit is usually inhibited after the capacitors attain full charge.

insert core—An iron core used generally for adjusting an inductor to a fixed frequency. It consists of a threaded metal insert molded or cemented into one or both ends of the core.

insert earphones—Small earphones that fit partially inside the ear.

insertion delay—Also called inherent delay, intrinsic delay, and propagation delay. The interval for a circuit or instrument to respond with an output after being triggered either internally or externally. It is usually implied that the numerically expressed period is an irreducible minimum.

insertion force—1. Of a connector, the force needed to fully engage a connector plug and receptacle. Depending on the number, arrangement, and size of the contact pins, in addition to the strength of the springs,

their surface finish, and the rigidity of their mountings, the required mechanical insertion force will be dictated to a great extent by the life expectancy of the connectors, the intended use, the speed of insertion, and their immunity to shock and vibration. 2. The effort, usually measured in ounces, required to engage mating components.

insertion gain—The gain resulting from the insertion of a transducer in a transmission system is the ratio of the power delivered to that part of the system following the transducer to the power delivered to that same part before insertion. (If more than one component is involved in the input or output, the particular component used must be specified. This ratio is usually expressed in decibels.)

insertion loss—1. The difference between the power received at the load before and after the insertion of apparatus at some point in the line. 2. The loss in load power resulting from the insertion of a component, connector, or device. Insertion loss is expressed in decibels as the ratio of power received at the load before insertion to the power received at the load after insertion. 3. Signal-power loss resulting from connecting communication equipment with dissimilar impedance values. 4. A power loss that results from inserting a component into a previously continuous path or creating a splice in it.

insertion phase shift—The change in phase of an electric structure when inserted into a transmission system.

insertion switch—A process by which information is inserted into a computer by the manual operation of switches.

insertion tool—A small, hand-held tool used to insert contacts into a connector.

inside lead—*See* start lead.

inside spider—A flexible device placed inside a voice coil to center it with the pole pieces of a speaker.

in-situ tester—*See* in-circuit tester.

inspection chamber—In a spectrophotometer, the part in which the solution to be tested is placed for analysis.

inspectoscope—An instrument for viewing quartz crystals, while they are immersed in oil, to determine mechanical faults, the approximate direction of the optical axis, and regions of optical twinning.

instability—1. The measure of the fluctuations or irregularities in the performance of a device, system, or parameter. 2. An undesired change that occurs over a period of time and that is not related to input, operating conditions, or load.

instantaneous automatic gain control—Abbreviated instantaneous AGC. A portion of a radar system that automatically adjusts the gain of an amplifier for each pulse so that there is a substantially constant output-pulse peak amplitude with different input-pulse peak amplitudes. The circuit is capable of acting during the time in which a pulse is passed through the amplifier.

instantaneous companding—Companding that varies the effective gain in response to instantaneous values of the signal wave.

instantaneous contacts—Contacts that are actuated immediately when a starting signal is applied to a timer.

instantaneous disc—A blank recording disc that can be played back on a phonegraph immediately after being cut on a recorder.

instantaneous frequency—The rate at which the angle of a wave changes when the wave is a function of time. If the angle is measured in radians, the frequency in hertz is the rate of change of the angle divided by 2π .

instantaneous overcurrent relay—Also called rate-of-rise relay. A device that functions instantaneously on an excessive value of current or on an excessive rate

of current rise, thus indicating a fault in the apparatus of the circuit being protected.

instantaneous power—The power at the points where an electric circuit enters a region. It is equal to the rate at which the circuit is transmitting electrical energy into the region.

instantaneous power output—The rate at which energy is delivered to a load at a particular instant.

instantaneous readout—Readout by a radio transmitter at the instant the information to be transmitted is computed.

instantaneous recording—A recording intended for direct reproduction without further processing.

instantaneous sampling—The process of obtaining a sequence of instantaneous values of a wave. These values are called instantaneous samples.

instantaneous sound pressure—The total instantaneous pressure at a certain point, minus the static pressure at that point. The most common unit is the microbar.

instantaneous speech power—The rate at which the speaker is radiating sound energy at any given instant.

instantaneous speed variations—*See* ISV.

instantaneous start-stop rate—The maximum stepping rate that can be attained by an unloaded stepper motor from a standstill without losing synchronism with the field and without overshooting to the next step when coming to a stop.

instantaneous value—1. The magnitude, at any particular instant, of a varying value. 2. The value of voltage or current at a particular instant. If the selected instant is the time when the polarity of the waveform changes, this value will be zero.

instruction—1. Information that, when properly coded and introduced as a unit into a digital computer, causes the computer to perform one or more of its operations. All instructions commonly include one or more addresses. 2. A binary code applied to a logic circuit to affect its mode of operation. 3. A statement that specifies an operation and the values or locations of its operands. In this context, the term *instruction* is preferable to the terms *command* or *order*, which are sometimes used synonymously. 4. A set of bits that defines a computer operation and is a basic command understood by the CPU. It may move data, do arithmetic and logic functions, control I/O devices, or make decisions as to which instructions to execute next. 5. In a computer, a single order within a program. This order will be fetched from memory, decoded, and executed by the CPU. Instructions may be arithmetic or logical, and operate on registers, memory, I/O devices, or specify control operations. A sequence of instructions is a program. 6. A machine-language command executed by the microprocessor in a computer system.

instructional constant—Also called pseudoinstruction. In a computer, data stored in the program or instructional area that will be used only as a test constant.

instruction code—The list of symbols, names, and definitions of the instructions that are intelligible to a given computer or computing system.

instruction counter—A multiple-bit register that keeps track of the address of the current instruction. *See* control counter.

instruction cycle—The process of fetching an instruction from memory and executing it.

instruction deck—A set of punched cards containing a symbolic coded program to be read into a computer.

instruction fetch—*See* fetch.

instruction length—The number of words needed to store an instruction. It is one word in most computers,

but some will use multiple words to form one instruction. Multiple-word instructions have different instruction execution times depending on the length of the instruction.

instruction modification—A change in the operation-code portion of a computer instruction or command such that, if the routine containing the instruction or command is repeated, the computer will perform a different operation.

instruction register—1. In a computer, the register that temporarily stores the instruction currently being performed by the control unit of the computer. 2. A computer storage for the binary code for the operation to be performed. Usually this instruction represents the contents of the address just designated by the program counter. However, the contents of the instruction register or the program counter may be changed by the computations. This, of course, represents one of the key ideas of a stored-program computer—instructions, as well as data, can be operated on and subsequent operations will be determined by the results.

instruction repertoire—The instruction set for a computer.

instruction set—1. A means of describing computer capability. It consists of a listing of all the instructions the computer can execute. The basic operations that can be performed by a CPU. Necessary instructions are arithmetic, logical, test and branch, and moves. 2. The set of general-purpose instructions available with a given computer. In general, different machines have different instruction sets. The number of instructions only partially indicates the quality of an instruction set. Some instructions may only be slightly different from one another; others rarely may be used. Instruction sets should be compared using benchmark programs typical of the application to determine execution times and memory requirements.

instruction storage—The storage medium that contains basic machining instructions in coded form.

instruction time—The time required to fetch an instruction from memory and then execute it.

instruction word—A computer word that causes the computer to execute a particular operation. *See* word.

instrument—A device capable of measuring, recording, and/or controlling.

instrument approach—A blind landing—i.e., solely by navigational instruments, without visual reference to the terrain.

instrument-approach system—In navigation, a system furnishing vertical and horizontal guidance to aircraft during descent. Touchdown requires some other guidance.

instrumentation—1. The use of devices to measure the values of varying quantities, usually as part of a system for keeping the quantities within prescribed limits. 2. Adding code to a program for injecting data and collecting information, usually for dynamic analysis.

instrumentation amplifier—High accuracy analog amplifier with full differential inputs and gains ranging from 1 to 1000.

instrumentation bus—A dedicated bus tailored for the connection of measurement and control devices.

instrument chopper—A vibrating switch used for modulating, demodulating, and switching dc or low-frequency ac information in instrumentation. It is driven synchronously from an ac or pulsating dc source. The driven switching circuit is designed for low-level (0- to 10-volt) signal information.

instrument driver—Software module that converts the parameters in the object code to the specific instruction sequence needed to stimulate an instrument.

Instrumentation amplifier.

instrument error—The inaccuracy of an instrument.

instrument flight—A blind flight—i.e., one in which the pilot controls the path and altitude of the aircraft solely by instrument.

instrument lamp—A lamp that illuminates or irradiates an instrument.

instrument landing station—A special radio station for aiding in landing aircraft.

instrument landing system—Abbreviated ILS. A radionavigation system intended to aid aircraft in landing. It provides lateral and vertical guidance, including distance from the landing point. Consists of four ground radio transmitting stations at and in the vicinity of an airport, which radiate direction and position signals to approaching aircraft that are received on an instrument in the aircraft and alert the pilot to any deviation from the safe approach path to the correct touchdown point.

instrument landing system localizer—System of horizontal guidance embodied in the instrument landing system that indicates the horizontal deviation of the aircraft from its optimum path of descent along the axis of the runway.

instrument multiplier—*See* voltage-range multiplier.

instrument relay—A relay that operates on the principles employed in such electrical measuring instruments as the electro-dynamometer, iron-vane, and D'Arsonval meters.

instrument shunt—An internal or external resistor connected in parallel with the circuit of an instrument to extend its current range.

instrument switch—A switch disconnecting an instrument or transferring it from one circuit or phase to another.

instrument transformer—A transformer that reproduces, in its secondary circuit, the primary current (or voltage) with its phase relationship substantially preserved, suitable for utilization in measurement, control, or protective devices.

instrument-transformer correction factor—The factor by which a wattmeter reading must be multiplied to correct for the effect of the instrument-transformer ratio correction factor and phase angle.

instrument zero—The lower end of the measuring instrument's scale. Instrument zero may not coincide with zero value of the measured variable. Zero error is the error at instrument zero.

insulated—Separated from other conducting surfaces by a nonconductive material offering a high, permanent resistance to the passage of current and disruptive discharge.

Instrument transformers.

insulated carbon resistor—A carbon resistor encased in fiber, plastic, or other insulation.

insulated clip—A clip terminating in an insulated eye through which flexible cords or wires may be run and supported.

insulated enclosure—A special shielded enclosure design providing insulation against weather or providing maximum temperature stability. Usually prefabricated as an exterior building panel in modular construction.

insulated-gate field-effect transistor—Abbreviated IGFET. In general, any field-effect transistor that has an insulated gate regardless of the fabrication process.

Insulated-gate field-effect transistor.

insulated-substrate monolithic circuit—An integrated circuit that may be either an all-diffused device or a compatible structure so constructed that the components within the silicon substrate are insulated from one another by a layer of silicon dioxide, instead of the reverse-biased pn junctions used for isolation in other techniques.

insulated terminals—Solderless terminals provided with an insulated sleeve over the barrel to prevent a short circuit.

insulated wire—A conductor covered with a non-conductive material.

insulating material—1. A material on or through which essentially no current will flow. It is used to confine the flow of current within a conductor or to eliminate the shock hazard of a bare conductor. 2. Any composition primarily adapted for preventing the transfer of electricity therethrough, the useful properties of which depend on its chemical composition or atomic arrangement.

insulating sleeve—Tube or tape of insulating material placed around metal-enclosed capacitors to insulate the case electrically from other components and wiring.

insulating strength—The measure of the ability of an insulating material to withstand electrical stress without breaking down. It is defined in terms of the voltage per unit thickness necessary to initiate a disruptive discharge and usually is measured in volts per centimeter. See also dielectric strength; electric strength.

insulating tape—Tape that is wrapped around joints in insulated wires or cables. It is impregnated with an insulating material and covered with adhesive on one side.

insulating varnish—A varnish applied to coils and windings to improve their insulation (and, at times, their mechanical rigidity).

insulation—1. A nonconductive material that prevents the leakage of electricity from a conductor, provides mechanical spacing or support, or protects against accidental contact. 2. The use of a material that passes negligible current to surround or separate a conductor to prevent loss of current. 3. A material that offers high electric resistance, making it suitable for covering components, terminals, and wires to prevent the possible future contact of adjacent conductors resulting in a short circuit. 4. Material used to cover electrical wires to prevent electrical leakage and short circuiting and to reduce the danger of shock.

insulation displacement termination—A connector that has insulated wire is forced into a channel constructed so that ridges or teeth in the channel cut through or displace the insulation and make an air-tight contact with the wire.

insulation piercing—A crimping method in which lances pierce wire insulation, enter into the strands, and make electrical contact without stripping the wire.

insulation rating—The dielectric-strength and insulation-resistance values required to ensure satisfactory performance.

insulation resistance—1. The resistance offered by an insulating material to the flow of current resulting from an impressed dc voltage. 2. The ratio of the voltage applied between two electrodes in contact with a specific insulator to the total current between the electrodes. 3. Industrial specifications usually call for a certain minimum value (several thousand megohms) determined with a specific voltage applied. 4. The direct current resistance between the two terminals of a capacitor, or between either or both of the terminals and the capacitor case. 5. The ratio of dc voltage impressed across a capacitor to the resultant leakage current. For a particular capacitor design, the product of insulation resistance and capacitance (megohm-microfarad) is quite constant. 6. The electrical resistance of the insulating material (determined under specified conditions) between any pair of contacts, conductors, or grounding devices in various combinations.

insulation resistivity—The insulation resistance per unit volume of insulation.

insulation stress—The molecule separation pressure caused by a potential difference across an insulator. The practical stress on insulation is expressed in volts per mil.

insulation system—All of the insulation materials used to insulate a particular electrical or electronic product.

insulator—1. A material in which the outer electrons are tightly bound to the atom and are not free to move. Thus, there is negligible current through the material when a voltage is applied. The resistivity is greater than 10^8 ohm-cm and generally decreases when the temperature rises. 2. A nonconducting substance such as porcelain, plastic, glass, rubber, etc. 3. A material of such low electrical conductivity that current through it can

usually be neglected. 4. A material of low electrical conductivity designed for supporting a conductor, physically and electrically separating it from another conductor or object.

insulator arcing ring—A circular or oval metal part placed at one or both ends of an insulator to prevent current from arcing over and damaging it and/or the conductor.

insulator arcover—The flow of power current over an insulator in the form of an arc following a surface discharge.

insulating—See surface insulation.

insulelectrics—The science encompassing insulating materials in electrical insulation.

integer—A whole number, which may be positive, negative, or zero. It does not have a fractional part. Examples of integers: 1, 2, 48, -136, etc., but not $3/4$.

integral-cavity, reflex-klystron oscillator—A reflex-klystron oscillator in which tuning is accomplished by changing the physical dimensions of the resonant cavity. It is usually referred to as a diaphragm- or grid-gap-tuned klystron, since a flexible diaphragm is used to change the cavity dimension, i.e., the gap between the cavity grids.

integral circuit packages—Microcircuits assembled from discrete components and all circuits created essentially in an active or passive substrate.

integral contact—Current-carrying member of jack, switch, or relay. Usually a flat, flexible spring or other conducting member having no separate contacts attached at point of mating.

integral-external-cavity reflex oscillator—A reflex-klystron oscillator in which a fixed internal cavity is tightly coupled to a permanently attached external cavity. Tuning is achieved by varying a reactance probe in the external cavity.

integral-horsepower motor—A motor that is built into a frame and has a continuous rating of 1 horsepower.

integral resistor—An internal or external resistor preconnected to the electrical element and forming an integral part of the cup assembly to provide a desired electrical characteristic of a precision potentiometer.

integrated—A type of design in which two or more basic components or functions are physically, as well as electrically, combined—usually on one chassis, such as an integrated amplifier.

integrated amplifier—Also called, occasionally, a control amplifier, since it is an amplifier with controls. 1. An amplifier that embodies in a common housing the preamplifier and control section and the power amplifier. Some early amplifiers of large power were in two separate units, one the control unit with preamplifiers and the other the power amplifier. 2. A single component combining the functions and circuitry of a power amplifier and preamplifier. See also amplifier.

integrated circuit—Abbreviated IC. Also called functional device. 1. An electrical network—active or passive—composed of two or more circuit elements inextricably bound on a single semiconductor substrate. To further define the nature of an integrated circuit, additional modifiers may be prefixed. Examples: dielectric-isolated monolithic integrated circuit, beam-lead monolithic integrated circuit, or silicon-chip tantalum thin-film hybrid integrated circuit. See also film integrated circuit; hybrid integrated circuit; monolithic integrated circuit; multichip integrated circuit. 2. Any electronic device in which both active and passive elements are contained in a single package. The term frequently is used for circuits other than those containing semiconductors; for example, microwave

insulator arcing ring — integrated morphology

designers consider many types of waveguide assemblies to be integrated circuits. 3. A small chip of solid material (generally a semiconductor) upon which, by various techniques, an array of active and/or passive components has been fabricated and interconnected to form a functioning circuit. Integrated circuits, which are generally encapsulated with only input, output, power supply, and control terminals accessible, offer great advantages in terms of small size, economy, and reliability. 4. The physical realization of a number of electrical circuit elements inseparably associated on or within a continuous body of semiconductor material to perform the function of a circuit. 5. An electronic device containing several elements, active or passive, that perform all or part of a circuit function. 6. An interconnected array of conventional components—transistors, diodes, capacitors, and resistors—fabricated *in situ* within and on a single crystal of semiconductor material with the capability of performing a complete electronic circuit function. 7. An electronic circuit containing transistors, diodes, resistors, and perhaps capacitors and photocells, along with interconnecting electrical conductors processed and contained entirely within a single chip of silicon. 8. Multiple, interconnected circuit elements, contained on or in a common substrate, that function as a unit and not separately.

integrated-circuit array—Multiple integrated circuits formed on a common substrate and electrically interconnected during fabrication.

integrated-circuit package—The combined mounting and housing for an integrated circuit; the package protects the integrated circuit and permits external connections to be made to it.

integrated communication system—Communication system on either a unilateral or joint basis in which a message can be filed at any communications center in that system and be delivered to the addressee(s) by any other appropriate communication center in that system without reprocessing en route.

integrated component—A number of electrical elements comprising a single structure that cannot be divided without destroying its stated electronic function.

integrated console—Computer control console that is capable of controlling the operation of the switching center equipment of an integrated communications system.

integrated data processing—A method of transforming disjointed and repetitive paperwork tasks into a correlated and mechanized production of information for any purpose.

integrated electronic component—Abbreviated IEC. An assembly that consists of several integrated circuits interconnected on a single chip of silicon to provide a complete electronic function with a circuit content greater than 10 equivalent gates.

integrated electronics—That portion of electronic art and technology in which the interdependence of material, device, circuit, and system-design considerations is especially significant; more specifically, that portion of the art dealing with integrated circuits.

integrated electronic system—See integrated circuit.

integrated equipment components—Abbreviated IECs. Integrated-circuit chips that contain a complete logic function.

integrated injection logic—See I²L.

integrated microcircuit—See integrated circuit.

integrated morphology—The structural characterization of an electronic component in which the identity of the current- or signal-modifying areas, patterns, or volumes has become lost in the integration of electronic

materials, in contrast to an assembly of devices performing the same function.

integrated optical circuit—Abbreviated IOC. Also called optical integrated circuit. A circuit, or group of interconnected circuits, consisting of miniature solid-state optical components, such as light-emitting diodes, optical filters, photodetectors (active and passive), and thin-film optical waveguides on semiconductor or dielectric substrates.

integrated optics—The interconnection of miniature optical components via optical waveguides on transparent dielectric substrates, using optical sources, modulators, detectors, filters, couplers, and other elements incorporated into circuits analogous to integrated electronic circuits, for the execution of various communication, switching, and logic functions.

integrated services digital network—Abbreviated ISDN. A switched network providing end-to-end digital connectivity for simultaneous transmission of voice and data over multiplexed communications channels. *See also* ISDN.

integrated software—An applications software package containing programs to perform more than one function.

integrated transducers—Semiconductor components that change the form of energy (e.g., piezoelectric devices, photogenerators, thermistors, etc.) and that are integrated into multifunction chips.

integrated voltage regulator—Abbreviated IVR. An integrated structure that serves as the reference, error amplifier, and shunt elements for shunt voltage regulation. A resistive voltage divider connected to its input provides adjustment of the output voltage.

integrating circuit—*See* integrator, 1.

$$E_{OUT} = \frac{1}{T} \int E_{IN} dt$$

$$(T = RC)$$

Formula.

Integrating circuits.

integrating meter—A meter that adds up (integrates) the electrical energy used over a period of time. An ordinary electric watt-hour meter is an example.

integrating motor—A motor that maintains a constant ratio of output-shaft rotational speed to input signal.

Thus, the angle of rotation of the shaft is proportional to the time integral of the input signal.

integrating photometer—A photometer that, with a single reading, indicates the average candlepower from a source in all directions or at all angles in a single plane.

integrating relay—A relay that sums up the inputs of voltage or current supplied to it and opens or closes its contacts in response to the input so integrated.

integrating-sphere densitometer—A photoelectric instrument that measures the density of motion-picture film or its sound track.

integration time—That time during which all electrons formed by impinging photons are gathered in a potential well under an energized electrode.

integrator—1. A device with an output proportionate to the integral of the input signal. 2. In certain digital machines, a device that numerically approximates the mathematical process of integration. 3. A device that determines on a continuous basis the total value of a quantity being measured, usually as a function of time. 4. Device for summing or totalizing counts, areas under curves, etc.

intelligence bandwidth—The total audio (or video) frequency bandwidths of one or more channels.

intelligence sample—Part of a signal taken as evidence of the quality of the whole.

intelligence signal—Any signal that conveys information (e.g., voice, music, code, or television).

intelligent controller—Device controller equipped with local interpreting functions, such as editing, input validity checks, and complex command decoding.

intelligent instruments—Devices that possess capabilities that raise them above the level of instruments that merely sense and display analog information. The following list presents one instrument intelligence rating system, from the lowest order of intelligence to the highest:

1. The ability to sense and display information.
2. Conversion of analog information into digital.
3. Mathematical manipulation of digital data.
4. Interpretation of results of mathematical manipulation.

5. Making of decisions on the basis of interpretation.

intelligent robot—A robot that can make decisions by itself through its sensing and recognizing capabilities.

intelligent terminal—1. An input/output device in which a number of computer processing characteristics are physically built into, or attached to, the terminal unit. 2. Programmable control terminal that drives other terminals, peripherals, floppy disks, machines, program counters, etc. 3. A programmable data service, usually

remote from the main computer, that unburdens the host computer by performing preliminary data processing such as formatting, verification, or validation. 4. A terminal that has editing and block-transmission capabilities, which allow manipulation of data in the terminal before transmission to the host computer. Some intelligent terminals can also perform checks on entered data. An intelligent terminal's programmability is restricted to formatting data on its screen. These formats can be called up through the keyboard and can have protected fields that allow entering of data (numeric, alphabetic, or alphanumeric) in the prescribed format. User programmability distinguishes the intelligent terminal from its less intelligent relatives. In addition to this programmability, an intelligent terminal has editing functions similar to those of a smart terminal. 5. An input/output device with built-in intelligence in the form of a microprocessor and able to perform functions that would otherwise require the central computer's processing power; sometimes called a stand-alone terminal. 6. A terminal with local processing power whose characteristics can be changed under program control.

intelligent time-division multiplexer—See ITDM.

intelligent voice terminal—Intelligent terminal operated by the human voice; software resident in the terminal is user-programmable. Best for applications suiting an intelligent terminal but where hands-free data entry is cost advantageous.

intelligibility—See articulation.

INTELSAT—Abbreviation for *International Telecommunications Satellite Consortium*. 1. A series of commercial communications satellites designed to relay telephony and television signals among the member INTELSAT nations. The INTELSAT global network employs an equatorial orbit above the Atlantic, Pacific, and Indian Oceans. Satellites in these three locations are capable of linking virtually all the inhabited areas of the world. 2. International (primarily noncommunist) satellite agency whose member nations lease transponder capacity on its satellite system to provide at least some TV in all parts of the world.

INTELSAT satellite.

intensifier electrode—Also called postaccelerating electrode. In some types of electrostatic cathode-ray tubes, an electrode that permits additional acceleration of the

electron beam after it has been deflected. This electrode emits greater intensity of the trace without materially reducing the deflection sensitivity of the tube.

intensifying screen—A thin fluorescent screen placed next to a photographic plate to increase the effect of radiation on the plate.

intensitometer—Also called a dosage meter or dosimeter. An instrument that estimates the amount of X-ray radiation, for determining the duration of exposure during X-ray pictures or therapy.

intensity—1. The strength of a quantity. 2. The relative strength, or amplitude, of electric, magnetic, or vibrational energy. 3. The brilliance of an image on the screen of a cathode-ray tube. 4. The strength of light or other electromagnetic energy being radiated or reflected per steradian. 5. The flux per unit solid angle radiating (diverging) from a source of finite area.

intensity control—Used with cathode-ray tubes to control the intensity of the electron beam and hence the amount of light generated by the fluorescent screen. Generally, the grid bias of the tube is regulated.

intensity level—Ratio of the intensity of the sound to a reference intensity of a free plane wave of 1 microwatt per square centimeter under normal conditions. Commonly expressed in decibels.

intensity modulation—1. The process and/or effect of varying the electron-beam current in a cathode-ray tube, resulting in varying brightness or luminance of the trace. 2. The process in which the electron beam of a cathode-ray tube is varied in intensity in accordance with the magnitude of the signals it receives. See also Z-axis modulation.

intensity of radiation—The radiant energy emitted in a specified direction per unit time, per unit area of surface, per unit solid angle.

interaction—The effects two or more parts, components, etc., have on each other while each is performing a function.

interaction crosstalk—Crosstalk resulting from mutual coupling between two paths by means of a third path. For example, if a signal on pair 1 is coupled to pair 2, and then coupled from pair 2 to pair 3, where it is measured, it is known as interaction crosstalk.

interaction loss (of a transducer)—Expressed in decibels, it equals 20 times the logarithm (to the base 10) of the scalar value of the reciprocal of the interaction factor.

interaction space—In an electronic tube, the region where the electrons interact with an alternating electromagnetic field.

interactive—1. Pertaining to an application in which each entry elicits a response. An interactive system may also be conversational, implying continuous dialog between the user and the system. 2. A program or system that can ask questions of the user and then take action based on his response. *Conversational* is often used to mean the same thing. 3. Refers to those applications in which a user communicates with a computer program via a terminal, entering data and receiving responses from the computer. 4. Processing of data on a two-way basis, with human intervention redirecting the processing in a predetermined manner.

interactive debugger—A computer system software utility that permits a user to examine his or her task while it executes by stopping it at given points (usually called breakpoints) and displaying and changing memory/register contents.

interactive environment—A situation in which a computer continually responds to the user on receipt of directives from his or her terminal.

interactive graphics — 1. The use of a large-screen, high-precision CRT and its associated circuitry — usually linked to a large-scale computer system through a small control computer — on which both alphanumeric and vector data are displayed and manipulated. By using the data entry device, two- and three-dimensional geometric designs can be created, deleted, and modified in real time to achieve desired results. 2. The use of a display terminal in a conversational or interactive mode. 3. Capability to perform graphics operations directly on the computer with immediate feedback.

interactive operation — Also called conversational mode. Online operation in which there is a give-and-take between person and machine.

interactive system — 1. A system in which it is possible for the human user or the device serviced by the computer to communicate directly with the operating program. For human users, this arrangement is termed a conversational system. 2. A system in which a computer or operating program communicates bilaterally with a user.

interactivity — Computer programs, online services, and interactive TV in which the user can make inputs that direct subsequent delivery of services. Channel surfing is a crude form of interactivity. Internet and online services provide simple forms of interactivity, i.e., point-and-click.

interaxis error — The deviation from 90° perpendicularity of one set of resolver windings when excitation is applied to one of the other windings. For rotor interaxis error, one stator winding is excited; for stator interaxis error, one rotor winding is excited.

interbase current — In a junction tetrode transistor, the current that flows from one base connection to the other through the base region.

interbase resistance — Resistance between base 2 and base 1 of a unijunction transistor measured at a specified interbase voltage with $I_E = 0$.

interblock space — *See* IRG.

intercarrier noise suppression — The means of suppressing the noise resulting from increased gain when a high-gain receiver with automatic volume control is tuned between stations. The suppression circuit automatically blocks the audio-frequency output of the receiver when there is no signal at the second detector.

intercarrier sound system — A television receiving system in which use of the picture carrier and the associated sound-channel carrier produces an intermediate frequency equal to the difference between the two carrier frequencies. This intermediate frequency is frequency modulated in accordance with the sound signal.

intercellular massage — The ultrasonic stimulation of body cells. Sometimes called micromassage.

intercepting — Routing of a call or message placed for a disconnected or nonexistent destination to an operator position or a specially designated terminal or machine answering device.

intercepting trunk — A trunk to which a call made to a vacant number, a changed number, or a line out of order is connected so that action may be taken by an operator.

intercept operator — The telephone operator who requests the number called, determines the reason for the intercept, and relays the information to the calling party.

intercept receiver — Also called search receiver. A specially calibrated receiver that can be tuned over a wide frequency range in order to detect and measure enemy rf signals.

intercept service — In a telephone system, a service provided to subscribers whereby calls to disconnected stations or dead lines are either routed to an intercept operator for explanation or the calling party receives a distinctive tone signal or recorded announcement to indicate that he or she has made such a call.

intercept tape — A tape used for temporary storage of messages intended for trunk channels and tributary stations in which there is equipment or circuit trouble.

intercept trunk — *See* intercepting trunk.

intercharacter space — In telegraphy, the space between characters of a word. It is equal to three unit lengths.

intercom — *See* intercommunication system.

intercommunication apparatus — Equipment and systems for paging and intercommunication within a building, including audio, bell systems, pillow systems, and pocket page systems.

intercommunication system — Also called intercom. 1. A two-way communication system without a central switchboard, usually limited to a single vehicle, building, or plant area. Stations may or may not be equipped to originate a call, but can answer any call. 2. A system that permits selective speaker voice communication via wires between any pair of several stations, usually in the same building. The stations may be either master stations, which may initiate calls to any of a group of stations, or slave stations, which may initiate calls only to their master station. 3. A communication system that bridges the gap between a regular telephone system and the public address (PA) system it locates people and permits communication with them. Most often, it is installed as an adjunct to telephone and PA systems.

intercom wire — Wire used to connect communications instruments, telephones, telegraph, etc.

interconnecting wire — 1. Wires used for connections between subassemblies, panels, chassis, and remotely mounted devices. Does not necessarily apply to the internal connection of these units. 2. The physical wiring between components (outside a module), between modules, between units, or between larger portions of a system or systems.

interconnection — 1. Also called tie line. A transmission line connecting two electric systems or networks and permitting energy to be transferred in either direction. Larger interconnections are often called interties, giant ties, or regional interconnections. 2. The conductive path required to achieve connection from a circuit element to the rest of the circuit. 3. Also called intraconnection. The physical wiring between components (outside a module), between modules, between units, or between larger portions of a system or systems.

interconnection diagram — Diagram showing the identity of all units in a piece of electronic equipment and the connections between them.

interconnections (microelectronic) — Those conductors and connections that are not in continuous integral contact with the substrate or circuit elements of an integrated circuit.

interconnection system — The electrical and mechanical interconnection of any one or all of the six levels of interconnections generally common to electronic equipment. The six levels of interconnection are intramodule, module to motherboard, intramotherboard, motherboard to back panel, backpanel wiring, and input/output.

interdiction — Techniques to prevent nonsubscribers access to information/programs on cable or drop cables. Interdiction electronics are outside the consumer's house and can be addressable.

interdigital magnetron — A magnetron with anode segments around the cathode. Alternate segments are connected together at one end, and remaining segments at the opposite end.

interdigital transducer — Abbreviated IDT. A number of interleaved metal electrodes whose width and spacing is equal and uniform throughout the transducer pattern. When a harmonic voltage is applied

to the transducer terminals, the IDT pattern excites a periodic electric field that penetrates into the piezoelectric substrate. The substrate responds by periodically expanding and contracting in unison with these fields. With the proper choice of substrate orientation, this piezoelectric excitation gives rise to surface acoustic waves that propagate in the two directions normal to the IDT electrodes. The electric field can be produced by applying signals of opposite potential to two parallel metal electrodes formed in films deposited on the surface of the crystal. As the field is applied, the alternating signals send an acoustic wave across its surface; this wave is reconverted to an electric signal at a second pair of similar electrodes at the other end of the crystal. In practice, the transducer consists of several pairs of interleaved parallel electrodes, which give the transducer its name. The fingers, and the space between them, must be related to the size of a wave of the frequency desired. In certain applications the transducer fingers are less than a thousandth of a millimeter wide.

interelectrode capacitance—The capacitance between one electron-tube electrode and the next electrode toward the anode. The capacitance between the electrodes in an electron tube.

interelectrode coupling—Capacitive feedback from the plate of a tube to the grid. In triodes, this limits the maximum amplification possible without starting oscillation.

interelectrode leakage—The undesired current that flows between elements not normally connected in any way.

interelectrode transit time—The time required for an electron to travel between two electrodes.

interelement capacitance—The capacitance caused by the pn junctions between the regions of a transistor and measured between the external leads of the transistor.

interexchange channel—A channel connecting two different exchange areas.

interface—1. A point or device at which a transition between media, power levels, modes of operation, etc., is made. 2. The two surfaces on the contact sides of mating connectors that face each other when mated. 3. A common boundary between two or more items. May be mechanical, electrical, functional, or contractual. 4. A common aspect at the boundary between two systems involving intersystem communication—e.g., the interaction between research and development, basic and applied science, or engineering and systems development. 5. The physical and space boundary surrounding the system, subsystem, equipment, or component, through which all environmental and operational stimuli essential to the device or affecting its proper operation must propagate or interact with other related devices or structures. 6. The hardware for linking two units of electronic equipment; for example, a hardware component to link a computer with its input (or output) device. 7. The means of connection between two logic elements, often elements that belong to two different "families." 8. The hardware or software required to be able to communicate with, sense, or control external equipment. 9. A circuit that controls the flow and format of data between a computer and a terminal or other peripheral. 10. An electrical connection that permits a peripheral device or communications channel to be attached to a system. 11. An electronic assembly that ties an external device to a computer. 12. A common boundary between automatic data-processing systems or parts of a single system. In communications and data systems, it may involve code, format, speed, or other changes as required. 13. The junction or point of interconnection between two systems or equipments with different characteristics. They may differ with respect to voltage, frequency, operating speed,

interelectrode capacitance — interface system

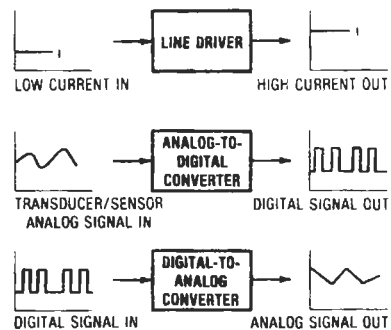

type of signal, and/or type of information coding. 14. To interconnect different systems to resolve their incompatibilities. 15. A common or shared boundary between two or more instruments, devices, or systems, which enables exchange of information among interconnecting units or systems that may not be directly compatible.

interface adaptor—Also called device adaptor. A unit that provides a mechanical and electrical interconnection between the tester and the device under test. It may include special stimulus, measurement, load, and switching circuitry unique to a device or family of devices but which is not provided in the tester.

interface analysis—Checking the interfaces between program elements (modules) for consistency and proper data transfer.

interface card—A device that converts a computer I/O bus into some standard I/O configuration (8- or 16-bit parallel BCD, RS-232, IEEE 488, etc.).

interface circuit—1. A circuit that links one type of logic family with another or with analog circuitry. 2. A circuit that allows two or more systems to be readily joined or associated. Examples include circuits that link linear and digital systems and those that enable communication between two circuits through a transmission line. 3. A circuit that links one type of device with another. Its function is to produce the required current and voltage levels for the next stage of circuitry from the previous stage. 4. An input/output circuit that permits different chips to communicate over a bus. 5. Linear or analog circuit with the prime function of supporting digital circuitry. Employed where the digital circuitry for the world of data processing and computation must meet the physical world of analog variables. Also used to mix functions from a number of digital logic families to obtain performance or economic benefits. There are at least nine different categories of interface circuits: bus interface, memory interface and control, line drivers and receivers, peripheral interface, numeric display interface, data converters, voltage reference, voltage comparators, and communications interface.

Interface circuits.

interface connection—Also called feedthrough. A conductor that connects patterns on opposite sides of a printed circuit board.

interface equipment—Equipment used between two other equipments that would otherwise be incompatible.

interface resistance—See cathode interface.

interface system—The device-independent mechanical, electrical, and functional elements of an interface necessary to effect communication among a set of devices. Cables, connector, driver and receiver circuits, signal

lines, descriptions, timing and control conventions, and functional logic circuits are typical interface system elements.

interface unit—A device that translates incoming signals that are incompatible with the electrical characteristics of the computer without changing the information content. Also translates outgoing signals for the benefit of associated equipment that is designed to different electrical standards.

interfacial bond—An electrical connection between the two faces of a substrate.

interfacial connection—In a printed circuit board, a conductor that connects conductive patterns on opposite faces of the base.

interfacial junction—The junction that is formed by the faces of the two mating halves of a connector. This junction can be tightly compressed or loose, depending on the requirements of the application of the connector.

interfacial seal—Sealing of a mated connector pair over the whole area of the interface to provide sealing around each contact. This is usually done by providing a soft insert material on one or both halves of the connector, which are in compression when mated.

interfacing—1. The joining of members of a group (people, instruments, and so on) in such a way that they are able to function in a compatible (synchronized) and coordinated fashion. 2. Interconnecting a program counter with its application devices and data terminals through various modules and cables. Interface modules convert program counter logic levels into external signal levels, and vice versa.

interference—1. Any electrical or electromagnetic disturbance, phenomenon, signal, or emission, man-made or natural, which causes or can cause undesired response, malfunctioning, or degradation of the electrical performance of electrical and electronic equipment. 2. Any signal that degrades the accuracy of a system. Interfering signals may be separated into two classes: damaging and degrading. Damaging signals cause degradation of accuracy after the signal is removed (even permanently). 3. Any undesired electrical signal induced into a conductor by electrostatic or electromagnetic means. 4. The additive process whereby the amplitudes of two or more overlapping waves are systematically attenuated and reinforced. 5. The process whereby a given wave is split into two or more waves by, for example, reflection and refraction of beam splitters, and then possibly brought back together to form a single wave. 6. Extraneous energy that tends to interfere with the desired signal. 7. Unwanted occurrences on communication channels that result from natural or human-made noises and signals.

interference blanker—A device used with two or more pieces of radio or radar equipment to permit simultaneous operation without confusion of intelligence, or used with a single receiver to suppress undesired signals.

interference eliminator—A device designed for the purpose of reducing or eliminating interference.

interference fading—Fading produced by different wave components traveling slightly different paths in arriving at the receiver.

interference filter—A device added between a source of human-made interference and a radio receiver to attenuate or eliminate noise signals. It generally contains a combination of capacitance and inductance.

interference guard band—See guard band.

interference pattern—1. The resultant space distribution of pressure, particle velocity, or energy flux when progressive waves of the same frequency and kind are superimposed. 2. The pattern produced on a radar scope by interference signals.

interference prediction—Estimation of the interference level of a particular item of equipment with respect to its future electromagnetic environment.

interference-rejection unit—Abbreviated IFRU. A tunable filter or wave trap capable of being adjusted to reject any frequency within the IF passband of a receiver while allowing the remainder of the passband curve to remain intact. It is adjusted to reject an interference signal and thus constitutes a form of antijamming.

interference source suppression—Techniques applied at or near a source of radiation to reduce its emission of undesired signals.

interference spectrum—The frequency distribution of the jamming interference in the propagation medium external to the receiver.

interferometer—An apparatus that shows interference between two or more wave trains coming from the same luminous area, and also compares wavelengths with observable displacements of reflectors or other parts.

interferometer homing—A homing guidance system in which the direction of the target is determined by comparing the phase of the echo signal as received at more than one antenna.

interferometer system—A method of determining the azimuth of a target through use of an interferometer to compare the signal phases at the output terminals of two antennas receiving a common signal from a distant source.

intergranular corrosion—A localized attack at metallic grain boundaries due to the presence of impurities and/or mechanical stress. On exposure to corrosive catalysis, the grain boundaries become anodic and the grains cathodic.

interior label—In a computer, a magnetically recorded sequence added to a tape to identify the contents.

interior-wiring-system ground—The ground connection to one of the current-carrying conductors of an interior wiring system.

interlace—1. In a computer, to assign successive storage location numbers to physically separated storage locations on a magnetic drum. This serves to reduce access time. 2. To transmit different interrogation modes on successive sweeps.

interlaced scanning—Also called line interlace. 1. A system of scanning whereby the odd- and even-numbered lines of a picture are transmitted consecutively as two separate fields. These are superimposed to create one frame, or complete picture, at the receiver. The effect is to double the apparent number of pictures and thus reduce flicker. 2. A scanning process in which the distance from center to center of successively scanned

Interlaced scanning.

lines is two or more times the nominal line width, and in which the adjacent lines belong to different fields.

interlace factor—A measure of the degree of interlace of normally interlaced fields.

interlace operation—A type of computer operation in which data can be read out of or copied into the memory without causing interference to the other activities of the computer. *See also* interrupt; time sharing, 1.

interlacing—A method of scanning used in television, in which each picture is divided into two or more complete sets of interlacing lines to reduce flicker.

interlayer connection—An electrical connection between conductive patterns in different layers of multilayer printed board. *See* through connection.

interleave—1. In a computer, to insert segments of one program into another program so that the two programs can be executed essentially simultaneously. 2. *See* interlace.

interleaving—1. Placing between. For example, in the transmission of a composite color signal, the bands of energy of the chrominance signal are interleaved with, or placed between, those of the luminance signal. 2. Assigning successive memory locations to different physical memory modules.

interlock—A device actuated by the operation of some other device with which it is directly associated, to govern succeeding operations of the same or allied devices. Interlocks may be either electrical or mechanical.

interlock circuit—A circuit in which a given action cannot occur until after one or more other actions have taken place. The interlocking action is generally obtained through the use of relays.

interlocking—The forcing of a voltage of one frequency to be in step with a voltage of another frequency.

interlock relay—1. A relay in which one armature cannot move or its coil be energized unless the other armature is in a certain position. 2. A relay with two sets of coils and respective armatures and contacts, so arranged that movement of one armature or energizing of its coil is dependent on the position of the other armature.

interlock switch—A safety switch that deenergizes a high-voltage supply when a door or other access cover is opened.

intermediate code—Machine input in a form between source and machine code; for example, pseudocode.

intermediate current—The range of current (milliamperes) at which formulation of carbonaceous material may significantly affect contact resistance.

intermediate fluxes—Fluxes consisting of mild organic acids and certain of their derivatives, such as the hydrohalides. As a class, they are weaker than the inorganic salt types.

intermediate frequency—Abbreviated IF. 1. A frequency to which a signal wave is shifted locally as an intermediate step in transmission or reception. 2. The fixed frequency resulting from heterodyning (i.e., beating or modulating to develop the sum or difference frequency signal) the incoming signal with a signal from the local oscillator. The IF used in FM tuners is commonly 10.7 MHz, and in AM tuners is 455 kHz. The IF signal is amplified in the IF channel, and it is here where most of the selectivity is introduced by tuned bandpass transformers and/or crystal or ceramic filters. 3. In superheterodyne receiving systems, the frequency to which all selected signals are converted for additional amplification, filtering, and eventual detection.

intermediate-frequency amplifier—1. An amplifier tuned to a fixed frequency, or capable of single-control tuning over a range of frequencies, for the purpose of selecting one of the frequency components generated in a mixer circuit. 2. The central stages of a superheterodyne radio receiver that amplify the signals after they have been converted to a fixed intermediate frequency by a mixer (frequency converter).

intermediate-frequency harmonic interference—Interference caused in superheterodyne receivers by the radio-frequency circuit accepting harmonics of the intermediate-frequency signal.

intermediate-frequency interference ratio—*See* intermediate-frequency response ratio.

intermediate-frequency jamming—A form of jamming in which two cw signals are transmitted at frequencies separated by an amount equal to the center frequency of the IF amplifier in the radar receiver.

intermediate-frequency response ratio—Also called intermediate-frequency interference ratio. In a heterodyne receiver, the ratio of intermediate-frequency signal input at the antenna to the desired signal input for identical outputs.

intermediate-frequency strip—Also called IF strip. A subassembly containing the intermediate-frequency stages in a receiver.

intermediate-frequency transformer—Also called IF transformer. A transformer designed for use in the intermediate-frequency amplifier of a superheterodyne receiver.

intermediate-frequency transformer-lead color code—Transformer leads in many radio receivers are identified by the following standard EIA colors:

Blue: Plate Green: Grid or diode
Red: B + Black: Grid return
Green-black: Second diode (full-wave transformers only)

Intermediate-frequency amplifier.

intermediate horizon—A screening object (such as a hill, mountain, ridge, building, etc.) similar to the radar horizon but nearer to the radar site. For example, a distant mountain range might be the radar horizon on a given azimuth, while a nearer, lower ridge might screen a valley between it and the mountain range; the ridge would be an intermediate horizon.

intermediate means—All system elements needed to perform distinct operations in the measurement sequence between the primary detector and the end device.

intermediate repeater—A repeater used other than at the end of a trunk or line.

intermediate state—The partial superconductivity that occurs when a magnetic field of appropriate strength is applied to a sphere of material below its critical temperature (i.e., the temperature below which the material would superconduct if no magnetic field were present).

intermediate storage—The portion of the computer storage facilities in which information in the processing stage usually is stored.

intermediate subcarrier—A carrier used for modulating a carrier or another intermediate subcarrier. It also may have been modulated by one or more subcarriers.

intermediate switching region—In a relay, an area between low level (including dry circuit) and power switching (including full rated load) where the contact arc does not destroy deposits that are byproducts of the switching function.

intermediate trunk distributing frame—A frame in which are mounted terminal blocks for connecting linefinders and first selectors.

intermetallic bond—The ohmic contact made when two metal conductors are welded or fused together.

intermetallic compound—A compound of two or more metals that has a characteristic crystal structure that may have a definite composition corresponding to a solid solution, often refractory.

intermittent—1. Occurring at intervals. 2. Electrical connections when conducting paths alternately open and close at some essentially uncontrolled rate. (Intermittents are undesirable since continuous connections are normally required.) 3. Not continuously present; disappearing and reappearing.

intermittent current—A unidirectional current that is interrupted at intervals.

intermittent defect—A defect that depends on variable conditions in a circuit. Hence, it is not present at all times.

intermittent duty—Operation for specified alternate intervals of load and no-load; load and rest; or load, no-load, and rest.

intermittent-duty rating—The output rating of a device operated for specified intervals rather than continuously.

intermittent-duty relay—A relay that must be deenergized at intervals to avoid excessive temperature, or a relay that is energized at regular or irregular intervals, as in pulsing.

intermittent pulsing—The transmission of short bursts of radiation at irregular intervals.

intermittent rating—The permissible output of a piece of apparatus when it is operated for alternate periods of load and rest that have a definite ratio to each other, or when it is run for a stated period of time that is not long enough to produce the final temperature.

intermittent reception—A defect in which the receiver operates normally for a while, at regular or irregular intervals.

intermittent scanning—One or two 360° scans of an antenna beam at irregular intervals to make detection by intercept receivers more difficult.

intermittent-service area—An area still receiving the ground wave of a broadcast station, but subject to interference and fading.

intermod—Abbreviation for intermodulation distortion (IMD). Interference that results when strong signals from a nearby transmitter mix with the desired signal in a radio receiver.

intermodulation—Sometimes called intermod. 1. In a nonlinear transducer element, the production of frequencies corresponding to the sums and differences of the fundamentals and harmonics of two or more frequencies transmitted through the transducer. 2. An error form that occurs in chopper-stabilized amplifiers when a beat component forms between the chopper drive frequency and normal signals that have frequencies near that of the chopper. 3. Mixing of two radio signals to produce a third signal that interferes with the reception of a desired signal.

intermodulation distortion—Abbreviated IMD. 1. Nonlinearity characterized by the appearance of frequencies in the output equal to the sums and differences of integral multiples of the component frequencies in the input signal. (Harmonics are usually not included.) 2. The introduction of unwanted signal energy as the result of interaction between two or more simultaneously reproduced tones, causing a smearing or veiling of the sound. All recording and amplifying equipment produces a certain amount of intermodulation distortion, but it can be held to sufficiently low levels to be below the threshold of audibility. 3. An analog-line impairment in which two frequencies interact to create an erroneous frequency, which in turn distorts the data-signal representation. 4. The production of spurious frequencies, not present in the original sound, that result from the interference or interaction of two (or more) sound signals that simultaneously occur in the original. These generally are sum and difference frequencies. For example, a 200-Hz and 75-Hz signal may occur at the same instant. If the equipment is prone to intermodulation distortion, these two may interact to produce a spurious 125-Hz tone. 5. The distortion caused by the addition of sum and difference modulation products when a complex wave (composed of two or more sine waves) passes through a nonlinear circuit. (When the modulation products are few, distortion is created; when they are many, noise is created.) 6. Distortion that results when two or more pure tones produce new tones with frequencies representing the sum and difference of the original tones and their harmonics.

intermodulation frequencies—The sum and difference frequencies generated in a nonlinear element.

intermodulation interference—The combination-frequency tones produced at the output by a nonlinear amplifier or network when two or more sinusoidal voltages are applied at the input. Generally expressed as the ratio of the root-mean-square voltage of one or more combination frequencies to that of one of the parent frequencies measured at the output.

intermodulation noise—Noise introduced in the channel of interest by signals being transmitted in other channels.

internal arithmetic—Any computations performed by the arithmetic unit of a computer, as distinguished from those performed by peripheral equipment.

internal calibration—Calibration by an internal voltage source (provided with the instrument) rather than an external standard.

internal connection—Abbreviated IC. In a vacuum tube, a base-pin connection designed not to be used for any circuit connections.

internal correction voltage—The voltage added to the composite controlling voltage of an electron tube.

It is the voltage equivalent of those effects produced by initial electron velocity, contact potential, etc.

internal graticule—A graticule whose rulings are a permanent part of the inner surface of the cathode-ray tube faceplate.

internal input impedance—The actual impedance at the input terminals of a device.

internally caused contact chatter—That chatter resulting from the operation or release of the relay. It may be classified as initial, armature-impact, armature-rebound, or armature-hesitation chatter.

internally stored program—A sequence of instructions (program) stored inside a computer in the same storage facilities as the computer data, as opposed to being stored externally on punched paper tape, pin boards, etc.

internal magnetic recording—Storage of information within the material itself, such as used in magnetic cores.

internal memory—Also called internal storage. The total memory or storage that is automatically accessible to a computer. It is an integral physical part of the computer and is directly controlled by it.

internal node—A junction between internal logic elements within an integrated circuit.

internal output impedance—The actual impedance at the output terminals of a device.

internal photoelectric effect—The creation of free electrons within a solid by the absorption of a sufficient amount of photons. The effect produces an increase in the conductivity of the solid.

internal resistance—1. The effective series resistance in a source of voltage. 2. The resistance of a voltage source, such as a generator, battery or power supply, which acts to reduce the terminal voltage of the source as current is drawn.

internal storage—Also called main memory and core memory. 1. Storage facilities in a computer forming an integral physical part of and directly controlled by the computer. 2. The total storage automatically available to the computer. *See also* internal memory.

internal timer—In a computer, the internal clock equipped with multiple registers that can monitor the duration of external events or generate a pulse after a fixed time.

international broadcast station—A station licensed for transmission of broadcast programs for international public reception. By international agreement, frequencies are allocated between 6000 and 26,600 kHz.

international call sign—The identifying letters and numbers assigned to a radio station in accordance with the International Telecommunications Union. The first character, or the first two, identify the nationality of the station.

international code signal—A code, adopted by many nations for international communication, in which combinations of letters are used in lieu of words, phrases, and sentences.

international communication service—A telecommunication service between offices or stations (including mobile) belonging to different countries.

international control station—A fixed station in the Fixed Public Control Service, directly associated with the International Fixed Public Radio Communication Service.

international coulomb—The quantity of electricity passing any section of an electric circuit in 1 second when the current is 1 international ampere. One international coulomb equals 0.99985 absolute coulomb.

international farad—The capacitance of a capacitor when a charge of 1 international coulomb produces a potential difference of 1 international volt between the

terminals. One international farad equals 0.99952 absolute farad.

International Fixed Public Radiocommunication Service—A fixed service, the stations of which are open to public correspondence, intended to provide radiocommunication between the United States or its territories and foreign points.

international henry—The inductance that produces an electromotive force of 1 international volt when the current is changing at a rate of 1 international ampere per second. One international henry equals 1.00018 absolute henrys.

international joule—The energy required to transfer 1 international coulomb between two points having a potential difference of 1 international volt. One international joule equals 1.00018 absolute joules.

International Morse code—Also called continental code. 1. A system of dot-and-dash signals used chiefly for international radio and wire telegraphy. It differs from American Morse code in certain code combinations only. 2. The Morse code that matches the English-language alphabet.

international ohm—The resistance at 0°C of a column of mercury of uniform cross section 106.300 centimeters in length and with a mass of 14.4521 grams. One international ohm equals 1.00048 absolute ohms.

International Radio Consultative Committee—Abbreviated CCIR. An international committee that studies technical operating and tariff questions pertaining to radio, broadcast television, and multichannel video transmissions and that issues recommendations. It reports to the International Telecommunications Union.

international radio silence—Three-minute periods of radio silence, commencing 15 and 45 minutes after each hour, on a frequency of 500 kHz only. During this time all radio stations are supposed to listen on that frequency for distress signals of ships and aircraft.

international system (of electrical and magnetic units)—A system for measuring electrical and magnetic quantities by using four fundamental quantities. Resistance and current are arbitrary values that correspond approximately to the absolute ohm and the absolute ampere. Length and time are arbitrarily called centimeter and second. The international system of electrical units was used between 1893 and 1947. By international agreement, it was discarded on January 1, 1948, in favor of the mksa (Giorgi) system.

international telecommunication service—A telecommunication service between offices or stations in different states, or between mobile stations that are not in the same state or that are subject to regulation by different states.

International Telecommunications Satellite Consortium—*See* INTELSAT.

International Telecommunication Union—The United Nations specialized agency that deals with telecommunications. Its purpose is to provide standardized communications procedures and practices, including frequency allocation and radio regulations on a worldwide basis.

International Telegraph Consultative Committee—Abbreviated CCIT. An international committee responsible for studying technical operating and tariff questions pertaining to telegraph and facsimile and issuing recommendations. It reports to the International Telecommunications Union.

international telephone address—A code not exceeding 12 digits that specifies a unique address for any telephone in the world. It consists of (a) a country or regional identity code of one, two, or three digits; (b) a three-digit numbering plan area code; (c) a two- or

three-digit central office code; plus (*d*) a four-digit station number.

International Telephone Consultative Committee—Abbreviated CCIF. An international committee responsible for studying and issuing recommendations regarding technical operations and tariff questions pertaining to ordinary telephones; carrier telephones; and music, picture, television, and multichannel telegraph transmission over wire line. It reports to the International Telecommunication Union.

international temperature scale—A temperature scale adopted in 1948 by international agreement. Between the boiling point of oxygen (-182.97°C) and 630.5°C it is based upon the platinum resistance thermometer. From 630.5°C to 1063.0°C it is based on the platinum rhodium thermocouple, and above 1063.0°C on the optical pyrometer.

international volt—The voltage that will produce a current of 1 international ampere through a resistance of 1 international ohm. One international volt equals 1.00033 absolute volts.

international watt—The power expended when 1 international ampere flows between two points having a potential difference of 1 international volt. One international watt equals 1.00018 absolute watts.

Internet—A vast collection of many computer networks that span the entire world and communicate across dedicated high-speed phone lines using a single protocol family called TCP/IP. The network used for electronic mail, file transfers, chat services, and general data communications. It consists of a backbone connected via gateways to many smaller networks such as LANs and WANs, and thus each network can access every other network.

Internet gateway—An online service that allows access to the Internet.

Internet protocol—*See* IP.

Internet service provider—*See* ISP.

internetworking—The technique of connecting individual LANs to form a larger network.

internode—Communication paths that originate in one node and terminate in another.

interoffice trunk—The telephone channel between two central offices.

interoperability—The ability of computer equipment from different manufacturers to work together compatibly.

interphase transformer—An autotransformer or a set of mutually coupled reactors used with three-phase rectifier transformers to modify current relationships in the rectifier system and thereby cause a greater number of rectifier tubes to carry current at any instant.

interphone—A telephone communication system wholly contained within an aircraft, ship, or activity.

interphone system—An intercommunication system like that in an aircraft or other mobile unit.

interpolate—To estimate the values of a function that are intermediate between those already known.

interpolation—1. The process of finding a value of a function between two known values. Interpolation may be performed numerically or graphically. 2. The process of determining a reading falling between two adjacent gradations on an analog meter scale.

interpole—A small auxiliary pole placed between the main poles of a direct-current generator or motor to reduce sparking at the commutator.

interposition trunk—A trunk connecting two positions of a large switchboard so that a line on one position can be connected to a line on the other position.

interpreter—1. A system program that converts and executes each instruction of a high-level language program into machine code as it runs, before going

on to the next instruction. An interpreted program is slow—as much as 20 times slower than an assembled program—but speeds up program development because the effect of source changes can be seen immediately. 2. A computer executive routine by which a stored program expressed in pseudocode is translated into machine code as a computation progresses, and the indicated operation is performed by means of subroutines as they are translated. 3. Programs that translate an assembled program into a complete machine-code listing on a line-by-line basis. If a statement is used in a program 10 times, it will be translated 10 times. 4. In a computer, a language translator that accepts high-level language (e.g., BASIC or Pascal) input text and translates this text into a special intermediate code that is simulated (interpreted) by a system program. Usually this intermediate code cannot be directly executed on a general-purpose processor. 5. A program that calls on subroutines to execute a program. Example: add two numbers, then divide by another number. BASIC is usually implemented as an interpreter. 6. A punch-card machine that will read the information conveyed by holes punched in a card and print its translation in characters arranged in specified rows and columns on the card.

interpreter code—A computer code that an interpretive routine can use.

interpretive programming—The writing of computer programs in a pseudo machine language, which the computer precisely converts into actual machine-language instructions before performing them.

interpretive routine—Computer routine designed to transfer each pseudocode and, using function digits, to set a branch order that links the appropriate subroutine into the main program.

interrecord gap—Also called interblock space. *See* IRG.

interrogate—1. To determine the state of a device or circuit. 2. To retrieve information from computer files by use of predefined inquiries or unstructured queries handled by a high-level retrieval language.

interrogation—The triggering of one or more transponders by transmitting a radio signal or combination of signals.

interrogation signal—A pulsed or cw signal emitted to initiate a reply signal from a transponder or responder.

interrogation suppressed time delay—The overall fixed time that elapses between transmission of an interrogation and reception of the reply to this interrogation at zero distance.

interrogator—Also called challenger. A radio transmitter used to trigger a transponder.

interrogator-responder—A combined radio transmitter and receiver for interrogating a transponder and displaying the replies.

interrupt—1. A processor feature that allows the currently executing program to be deferred in favor of servicing another. 2. A special instruction from a computer that temporarily disrupts normal operation and changes the normal flow of instruction execution. 3. In a computer, a break in the normal flow of a system or routine such that the flow can be resumed from that point at a later time. The source of the interrupt may be internal or external. 4. A method of stopping a process and identifying that a certain condition exists. In graphic systems, interrupts can originate from data entry devices, the display list, the host computer, the refresh clock, and display error conditions. When an interrupt occurs, the host computer and display refresh cease until the interrupt is answered and processed. At that time, the host computer will restart the refresh—usually from where it was halted.

If a new display list is to be presented, the display starts at the beginning of the list. 5. To stop a process in such a way that it can be resumed.

interrupted continuous waves—Abbreviated ICW. Continuous waves that are interrupted at an audio-frequency rate.

interrupt enable—See interrupt mark.

interrupter—1. A magnetically operated device used for rapidly and periodically opening and closing an electric circuit in doorbells and buzzers and in the primary circuit of a transformer supplied from a dc source. 2. A device used to produce interrupted ringing cycles. It also may be employed with the release alarm to start signal alarm circuits of the switching equipment and thereby provide timed delay in the sounding of a failure alarm. 3. An electrical, electronic, or mechanical device that periodically interrupts a continuous current to produce pulses. 4. A device that produces an electrical output signal when an object breaks the light (visible or invisible) between a light source and a photodetector.

interrupter contacts—On a stepping relay, an additional set of contacts operated directly by the armature.

interrupting capacity—The maximum power in the arc that can be interrupted by a circuit breaker or fuse without the occurrence of restriking or violent failure. Rated in volt-amperes for ac circuits and in watts for dc circuits.

interrupting rating—1. Conditions under which the contact of a relay must interrupt with a prescribed duty cycle and contact life. 2. The amount of current that a fuse can interrupt without the fuse cartridge rupturing or showing any external sign of damage.

interrupting time—In a circuit breaker, the interval between the energizing of the trip coil and the interruption of the circuit, at the rated voltage.

interrupt latency—The delay between an interrupt request and acknowledgment of the request.

interrupt mark—A mechanism that allows a program to specify whether or not an interrupt request will be accepted by the computer (sometimes called interrupt enable).

interrupt request—A signal to a computer that temporarily suspends the normal sequence of a routine and transfers control to a special routine. Operation can be resumed from this point later. Ability to handle interrupts is very useful in communication applications, where it allows the microprocessor to service many channels.

Interrupt vector—1. Typically, two memory locations assigned to an interrupting device and containing the starting address and processor status word for its service routine. 2. A function that facilitates fast handling of external interrupts by having the hardware supply a value corresponding to the device causing the interrupt. This value then becomes an index into the interrupt vector that contains a pointer to the appropriate interrupt service routine.

interstage—Between stages.

interstage coupling—Coupling between stages.

interstage transformer—A transformer that couples two stages together.

interstation noise suppression—Canceling of the noise that occurs when a high-gain radio receiver with automatic volume control is tuned between stations.

interstitial site—A position that is inside a crystal lattice but is not one of the proper sites ordinarily occupied by the atoms of the crystalline material. Impurity ions of the proper size can occupy such positions in a lattice that is otherwise regular.

intersymbol interference—1. In a transmission system, extraneous signal energy during one or more

keying intervals that tends to hinder the reception of the signal in another keying interval. 2. The disturbance that results from this condition.

interties—See interconnection, 1.

intertoll trunk—A trunk linking toll offices in different telephone exchanges.

interval—A period from one event to another. An interval timer controls the time a load is energized or deenergized.

interval calibration—See step calibration.

interval circuit—A circuit that is energized during timing only. This can be accomplished by using a timer with interval contacts, or by using a timer with delayed contacts in series with the start switch, or one with instantaneous contacts in series with delayed contacts.

interval contacts—In a timer, contacts that are actuated only for the duration of the preset time interval.

interval timer—1. A device for measuring the time interval between two actions. 2. A timer that switches electrical circuits on or off for the duration of the preset time interval. 3. A hardware or software clock that generates an interrupt after a specified period has elapsed.

interword space—In telegraphy, the space between words or coded groups. It is equal to seven unit lengths.

intonation—The slight modification of pitch, or frequency, that makes a note sound flat or sharp compared with the natural frequency of the note played.

intracardiac—Pertaining to instruments whose pickup element is inserted through a vein directly into the heart chambers.

Intraconnections (microelectronics)—1. Those conductors and connections that are in continuous integral contact with the substrate or circuit elements of an integrated circuit. 2. See interconnection.

intraoffice trunk—Telephone channel used to interconnect two customer lines within the same central office.

intrinsically safe—Incapable of releasing sufficient electrical energy to ignite a specific atmospheric mixture under normal conditions or such abnormal conditions as accidental damage to any part of the equipment or wiring insulation, failure of electrical components, application of overvoltage, or improper adjustment or maintenance operations.

intrinsic-barrier diode—A pin diode in which a thin region of intrinsic material separates the n-type and p-type regions.

intrinsic-barrier transistor—A pnp or npn transistor in which a thin region of intrinsic material separates the collector from the base.

intrinsic brightness—The luminous intensity measured in a given direction per unit of apparent (projected) area when viewed from that direction.

intrinsic characteristics—Characteristics of a material that depend on the material itself and do not result from impurities.

intrinsic coercive force—The magnetizing force that, when applied to a magnetic material in a direction opposite to that of the residual induction, reduces the intrinsic induction to zero.

intrinsic coercivity—The measurement (in oersts) of the force required to reduce the intrinsic induction of the magnetized material to zero.

intrinsic concentration—In a semiconductor, the number of minority carriers that exceeds the normal equilibrium number.

intrinsic conduction—In an intrinsic semiconductor, the conduction associated with the directed movement of electron-hole pairs under the influence of an electric field.

intrinsic contact potential difference—The true potential difference between two spotlessly clean metals in contact.

intrinsic delay—*See* insertion delay.

intrinsic detector—A photodetector composed of a photoconductive material that, when exposed to radiation, conducts without the aid of added impurities and does not have to be cooled to the level of extrinsic material. Examples of intrinsic materials are silicon and cadmium sulfide.

intrinsic electric strength—The characteristic electric strength of a material.

intrinsic flux—The product of the intrinsic flux density and the cross-sectional area of a uniformly magnetized sample of material.

intrinsic flux density—In a sample of magnetic material, the excess of the normal flux density over the flux density in a vacuum for a given magnetizing field strength. In the cgs system, the intrinsic flux density is numerically equal to the difference between the ordinary flux density and the magnetizing field strength.

intrinsic hysteresis loop—A curve that shows intrinsic flux density as a function of magnetizing field strength, where the magnetizing field is cycled between equal values of opposite polarity. Hysteresis is indicated by the fact that the ascending and descending portions of the curve do not coincide.

intrinsic induction—The excess magnetic induction produced in a magnetic material by a given magnetizing force, over the induction that would be produced by the same magnetizing force in a vacuum.

intrinsic insulation—Any method of isolating fields or current within a semiconductor or other substrate. Among these are thermal oxidation, fabrication of an isolating layer of intrinsic semiconductor material, and creation of one or more back-based functions.

intrinsic-junction transistor—*See* intrinsic-region transistor.

intrinsic layering—The method of separating two regions of conductive semiconductor by a region of near-intrinsic semiconductor material. This material differs enough in resistivity from the adjacent regions to serve as an insulator.

intrinsic material—A semiconductor material in which there are equal numbers of holes and electrons, i.e., no impurities.

intrinsic mobility—The mobility of electrons in an intrinsic semiconductor or in a semiconductor having a very low concentration of impurities.

intrinsic noise—Noise that is due to the device or transmission path and is independent of modulation.

intrinsic permeability—Ratio of intrinsic normal induction to the corresponding magnetizing forces.

intrinsic photoconductivity—The absorption of a photon raising an electron across the forbidden gap from valence to conduction band of the semiconductor, whereby conductivity is increased and incident radiation may be measured.

intrinsic photoemission—The photoemission that would occur if a crystal were pure and its structure perfect.

intrinsic properties—The semiconductor properties that are characteristic of the pure, ideal crystal.

intrinsic Q—*See* unloaded Q (switching tubes).

intrinsic region—*See* i region; depletion region.

intrinsic-region transistor—Also called intrinsic-junction transistor. A four-layer transistor with an intrinsic region between the base and collector. Examples are npin, pnip, npip, and pnpin transistors.

intrinsic reliability—The probability that a device will perform its specified function, determined by

statistical analysis of the failure rates and other characteristics of the parts and components the device comprises.

intrinsic semiconductor—1. A semiconductor in which some hole and electron pairs are created by thermal energy at room temperature, even though there are no impurities in it. 2. A semiconductor with substantially the same electrical properties as those of the ideal crystal. 3. An element or compound that has the same electron energy band configuration as an insulator, but has a forbidden energy gap that is sufficiently narrow to permit transfer of electrons from the valence band to the conduction bands at normal temperatures. Conduction in an intrinsic semiconductor takes place via equal number of conduction band electrons and valence band holes.

intrinsic standoff ratio—In a unijunction transistor, the difference between the emitter voltage at the peak point with a specific interbase voltage and the forward voltage drop of the emitter junction, divided by the voltage on base 2 with respect to base 1.

intrinsic temperature range—The temperature range at which impurities or imperfections within the crystal do not modify the electrical properties of a semiconductor.

intrusion alarm system—An alarm system for signaling the entry or attempted entry of a person or an object into the area or volume protected by the system.

Invar—An alloy containing 63.8 percent iron, 36 percent nickel, and 0.2 percent carbon. Has a very low thermal coefficient of expansion. Used primarily as resistance wire in wirewound resistors.

inverse beta—The transistor gain that results when the emitter and collector loads are physically reversed in the operation of a circuit.

inverse common base—Transistor circuit configuration in which the base terminal is common to the input circuit and to the output circuit and in which the input terminal is the collector terminal and the output terminal is the emitter terminal.

inverse common collector—Transistor circuit configuration in which the collector terminal is common to the input circuit and to the output circuit and in which the input terminal is the emitter terminal and the output terminal is the base terminal.

inverse common emitter—Transistor circuit configuration in which the emitter terminal is common to the input circuit and to the output circuit and in which the input terminal is the collector terminal and the output terminal is the base terminal.

inverse direction of operation—A mode of operating a transistor in which the nominal collector region acts as an emitter and in which the net flow of minority carriers is from the nominal collector region to the base region.

inverse electrical characteristics—In a transistor, those characteristics obtained when the collector and emitter terminals are interchanged and the transistor is then tested in the normal manner.

inverse electrode current—The current flowing through an electrode in the opposite direction from that for which the tube was designed.

inverse feedback—*See* negative feedback.

inverse-feedback filter—A tuned circuit at the output of a highly selective amplifier having negative feedback. The feedback output is zero for the resonant frequency, but increases rapidly as the frequency deviates.

inverse Fourier transform—A mathematical operation that synthesizes a time-domain signal from its complex spectrum components. If a time-domain signal is Fourier transformed and then inverse Fourier transformed, the original time function is reconstructed.

inverse limiter—A transducer with a constant output for inputs of instantaneous values within a specified range. Above and below that range, the output is linear or some other prescribed function of the input.

inverse networks—Any two two-terminal networks in which the product of their impedances is independent of frequency within the range of interest.

inverse neutral telegraph transmission—A form of transmission in which zero-current intervals are used as marking signals, and current pulses of either polarity are used as spacing signals.

inverse-parallel connection—*See* back-to-back circuit.

inverse peak voltage—The peak instantaneous voltage across a rectifier tube during the nonconducting half-cycle.

inverse photoelectric effect—The transformation of the kinetic energy of a moving electron into radiant energy, as in the production of X-rays.

inverse piezoelectric effect—Contraction or expansion of a piezoelectric crystal under the influence of an electric field.

inverse ratio—The seesaw effect whereby one value increases as the other decreases or vice versa.

inverse-square law—1. The strength of a field, or the intensity of radiation, decreases in proportion to the square of the distance from its source. 2. The law stating that the illuminance (or irradiance) from a point source varies as the inverse square of the distance between the source and the receiver.

inverse time—A qualifying term applied to a relay, indicating that its time of operation decreases as the magnitude of the operating quantity increases.

inverse voltage—The effective voltage across a rectifier tube during the half-cycle when current does not flow.

inverse Wiedemann effect—*See* Wiedemann effect.

inversion—1. The bending of a radio wave because the upper part of the beam is slowed down as it travels through denser air. This may occur when a body of cold air moves in under a moisture-laden body of air. 2. The producing of inverted or scrambled speech by beating an audio-frequency signal with a fixed band of the resultant beat frequencies. The original low audio frequencies then become high frequencies and vice versa.

inversion layer—A layer of doped semiconductor material that has changed to the opposite type, such as a p layer at the surface of an n-doped region. Surface inversion layers may be the result of surface ions or dopant gettering by surface passivation material or the action of induced electric fields. *See also* channel, 6.

inverted amplifier—An amplifier stage containing two vacuum tubes. The control grids are grounded, and the driving excitation is applied between the cathodes. The grids then serve as a shield between the input and output circuits. Thus, the output-circuit capacitance is greatly reduced.

inverted-L antenna—An antenna consisting of one or more horizontal wires with a vertical wire connected at one end.

inverted speech—*See* scrambled speech.

inverter—1. A circuit that takes in a positive signal and puts out a negative one, or vice versa. 2. A device that changes alternating current to direct current or vice versa. It frequently is used to change 6-volt or 12-volt direct current to 110-volt alternating current. 3. A device that accepts an input that is a function of the maximum voltage and changes it into an output that is a function of both the maximum voltage and time. 4. A circuit with one input and one output, and whose function is to invert the

Inverted-L antenna.

input. When the input is high, the output is low, and vice versa. The inverter is sometimes called a NOT circuit, since it produces the reverse of the input. 5. A device or circuit that complements a Boolean function.

Inverter, 4.

inverter circuit—*See* NOT circuit.

inverting amplifier—An amplifier in which the output polarity is the opposite of the input polarity. Such an amplifier obtains negative feedback through a connection from the output to the input, and with high gain it is widely used as an operational amplifier.

inverting connection—The closed-loop connection of an operational amplifier when the forward gain is negative for dc signals. A 180° phase shift.

inverting input—An input terminal of a differential amplifier that produces an output signal of opposite phase (shifted 180°) than that of the input signal.

inverting parametric device—A parametric device whose operation depends essentially upon three frequencies: a harmonic of the pump frequency, and two signal frequencies, of which the higher signal frequency is the difference between the pump harmonic and the lower signal frequency.

invisible file—*See* hidden file.

invister—A high-frequency, high-transconductance unipolar structure made by means of lateral diffusion.

inward-outward dialing system—A dialing system by means of which calls within the local exchange area may be dialed directly to or from base private branch exchange telephone stations without the assistance of an operator at the base private branch exchange.

inward WATS—Inward wide area telephone service that permits a customer, for a monthly charge, to receive incoming station-to-station calls from telephones within prescribed service areas or in six interstate bands, without charge to the calling party. A telephone service similar to WATS but applicable to incoming calls only.

I/O or i/o—Abbreviation for input/output. 1. The components of a computer system's architecture that control the flow of data and instructions to and from the CPU. 2. Any equipment that introduces data into or extracts data from a data communications system.

IOC—*See* integrated optical circuit.

I/O device—Abbreviation for input/output device. 1. A disk drive, magnetic tape unit, printer, or similar

device that transmits data to or receives data from a computer or secondary storage device. 2. A general term for equipment used to communicate with a computer. 3. A device that supplies data and instructions to the computer and receives the computer's output, or a circuit that interfaces with such a device. 4. Input/output equipment used to communicate with a system.

I/O electrical isolation—Separation of the field wiring circuits from the logic level circuits of the PC, typically done with optical isolation.

I/O modules—General-purpose circuit modules that interface a microprocessor to relays, switches, and transducers. Each module contains almost all necessary interface circuitry in one package either to sense a load, control a switch, or condition a transducer signal so that practically no other interface design is required.

ion—1. An atom that has become charged by gaining or losing one or more orbiting electrons. A completely ionized atom is stripped of all electrons. 2. An atom or molecule with an electrostatic charge. 3. The charged particle formed when one or more electrons are taken from or added to a previously neutral atom or molecule. An atom that has gained additional electrons is thus a negative ion, whereas an atom that has lost an electron or electrons is a positive ion.

ion charging—In a storage tube, spurious charging or discharging caused by ions striking the storage surface.

ion counter—A tubular chamber for measuring the ionization of air.

ion-exchange electrolyte cell—A fuel cell that uses the reaction of hydrogen with oxygen from the air. It is similar to the standard hydrogen-oxygen fuel cell, except that an ion-exchange membrane replaces the liquid electrolyte. Operation is at atmospheric pressure and room temperature.

ionic conductivity—The transit phenomenon that occurs as a result of positive and/or negative charge movement in an electrolyte when placed in an electric field.

ionic focusing—Focusing the electron beam in a cathode-ray tube by varying the filament voltage and temperature to change the electrostatic focusing field automatically produced by the accumulation of positive ions in the tube.

ionic-heated cathode—A cathode that is heated primarily by bombardment with ions.

ionic-heated cathode tube—An electron tube containing an ionic-heated cathode.

ionic tweeter—A type of speaker in which a varying electrostatic field activates a mass of air ionized by a high-voltage radio-frequency field. Ionic speakers are capable of extremely extended high-frequency response (up to 100 kHz or so) because of the extreme lightness of the ionic "diaphragm."

ion implantation—1. A precise and reproducible method of semiconductor doping in which selected dopants are ionized and accelerated at high velocity to penetrate the semiconductor substrate and become deposited below the surface. Charged atoms (ions) of elements such as boron, phosphorus, or arsenic are accelerated by an electric field into the semiconductor material. This technique ensures uniform, accurately controlled depth of implantation and ionic diffusion in the wafer. 2. A processing step by which standard p-channel diffused MOS devices are made directly compatible with TTL/DTL logic. It is a highly controllable process that allows the adjusting of gate threshold voltages and also allows the fabrication of both enhancement-mode and depletion-mode transistors on the same chip. 3. A process that uses accelerated atoms to implant source and drain regions in metal-oxide semiconductors. It offers higher

speed and lower threshold voltages and can also be used with PMOS, NMOS, and CMOS.

Ion implantation.

ion-implanted MOS—Abbreviated IMOS. A method for doping substrates with a stream of ionized dopant atoms. Ions are electrically shot into the substrate instead of diffusing atoms at high temperatures.

ionization—1. The dissociation of inert-gas atoms into positive and negative ions in an electric field, resulting in the emission of light. 2. The state of an insulator in which it facilitates the passage of current because of the presence of charged particles (usually induced artificially). 3. The electrically charged particles produced by high-energy radiation (such as light or ultraviolet rays) or by the collision of particles during thermal agitation. 4. The formation of ions. The process of giving a net charge to a neutral atom or molecule by adding or subtracting an electron. This can be accomplished by radiation or by a strong electric field.

ionization arc—1. Formation of an electrical arc between terminals or contacts as a result of ionization of the adjacent air or gas. 2. Formation of an arc between the terminals of a satellite antenna as the satellite passes through the ionized regions of the ionosphere.

ionization chamber—1. An enclosure containing two or more electrodes between which an electric current may pass when the gas within is ionized. The current is a measure of the total number of ions produced in the gas by externally induced radiations. 2. A chamber containing a gas through which ionizing particles pass. A voltage is applied across the chamber so as to collect the ions produced and permit the ion current to be measured.

ionization current—The current resulting from the movement of electric charges, under the influence of an applied electric field, in an ionized medium.

ionization energy—Sometimes called ionization potential. The minimum amount of energy (usually expressed in electronvolts) required to eject an electron from a molecule.

ionization factor—The difference between percent power factors of a dielectric at two specified values of electrical stress. The lower of the two stresses is usually selected so that the effect of ionization on power factor at this stress is negligible.

ionization gage—1. A gage that measures the degree of a vacuum in an electron tube by the amount of ionization current in the tube. 2. A type of radiation detector that depends on the ionization produced in a gas by the passage of a charged particle through it. One

of the best known is the Geiger-Mueller counter. Cloud chambers and spark chambers can also be included in this category.

ionization-gage tube—An electron tube that measures low gas pressure by the amount of ionization current produced.

ionization potential—1. The energy, expressed in electronvolts, needed to remove one electron from a neutral atom or molecule in its ground state. 2. The amount of energy, for a particular kind of atom, required to remove an electron from the atom to infinite distance. The ionization potential is usually expressed in volts.

ionization pressure—An increase in the pressure in a gaseous discharge tube due to ionization of the gas.

ionization resistance—See corona resistance.

ionization smoke detector—A smoke detector in which a small amount of radioactive material ionizes the air in the sensing chamber, thus rendering it conductive and permitting a current through the air between two charged electrodes. This effectively gives the sensing chamber an electrical conductance. When smoke particles enter the ionization area, they decrease the conductance of the air by attaching themselves to the ions, causing a reduction in mobility. When the conductance is less than a predetermined level, the detector circuit responds.

ionization time—1. The time interval between the initiation and the establishment of conduction in a gas tube at some stated voltage drop for the tube. 2. The elapsed time to achieve normal glow after a voltage greater than the breakdown voltage is applied to a glow lamp.

ionization transducer—A transducer in which displacement of the force-summing member is sensed by the induced changes in differential ion conductivity.

Ionization transducer.

ionization vacuum gage—A gage in which the operation depends on the positive ions produced in a gas by electrons as they accelerate between a hot cathode and another electrode in a vacuum. It ordinarily covers a pressure range of 10^{-4} to 10^{-10} mm of mercury.

ionization voltage (corona level)—The minimum value of falling rms voltage that sustains electrical discharge within the vacuous or gas-filled spaces in the cable construction or insulation.

ionize—To free an electron from an atom or molecule (e.g., by X-ray bombardment) and thus transform the atom

or molecule into a positive ion. The freed electron attaches itself to another atom or molecule, which then becomes a negative ion.

ionized layers—Layers of increased ionization within the ionosphere. They are responsible for absorption and reflection of radio waves and are important for communication and for tracking satellites and other space vehicles.

ionizing event—Any interaction by which one or more ions are produced.

ionizing radiation—1. Radiant electromagnetic energy and high-energy particles that cause the division of a substance into parts carrying positive and negative charges. High-energy particles can directly ionize substances, whereas electromagnetic radiation sets in motion charged particles that then produce ions. 2. Generally, any radiation having sufficient energy to dislodge electrons from atoms or molecules while traveling through a substance, thereby producing ions.

ion migration—1. Movement of the ions produced in an electrolyte by application of an electric potential between electrodes. 2. The movement of free ions within a material or across the boundary between two materials under the influence of an applied electric field.

ionophone—A high-frequency speaker in which the audio-frequency signal modulates an rf supply to maintain an arc in the mouth of a quartz tube. The resultant modulated wave acts directly on the ionized air under pressure and thus creates sound waves.

ionosphere—The part of the earth's outer atmosphere where sufficient ions and electrons are present to affect the propagation of radio waves.

ionospheric absorption—The loss of energy of a radio wave as it travels through the atmosphere, setting particles in motion. The energy needed to create this motion is equal to the loss.

ionospheric disturbance—1. The variation in the state of ionization of the ionosphere beyond the normal observed random day-to-day variation from the average value for the location, date, and time of day under consideration. 2. Change in the part of the earth's outer atmosphere (ionosphere) that affects transmission and reception of radio signals.

ionospheric D scatter meteor burst—A phenomenon in which the penetration of meteors through the D region of the ionosphere affects ionospheric scatter communications.

ionospheric error—Also called sky error. In navigation, the total systematic and random error resulting from reception of the navigational signal after it has been reflected from the ionosphere. It may be due to variations in the transmission path, uneven height of the ionosphere, or uneven propagation within the ionosphere.

ionospheric prediction—The forecasting of ionospheric conditions and the preparation of radio propagation data derived from it.

ionospheric scatter—See forward scatter.

ionospheric storm—An ionospheric disturbance associated with abnormal solar activity and characterized by wide variations from normal, including turbulence in the F region and increases in absorption. Often the ionization density is decreased and the virtual height is increased. The effects are most marked in high magnetic latitudes.

ionospheric wave—Also called a sky wave. A radio wave that is propagated by way of the ionosphere.

ion sheath—A positive-ion film that forms on or near the grid of a gas tube and limits its control action.

ion spot—1. In camera or image tubes, the spurious signal resulting from bombardment of the target or photocathode by ions. 2. On a cathode-ray-tube screen,

an area where the luminescence has been deteriorated by prolonged bombardment with negative ions. 3. A spot on the fluorescent surface of a cathode-ray tube that is somewhat darker than the surrounding area because of bombardment by negative ions, which reduce the sensitivity.

ion trap—Also called a beam bender. 1. An electron-gun structure and magnetic field that diverts negative ions to prevent their burning a spot in the screen, but permits electrons to flow toward the screen. 2. An arrangement of magnetic fields and apertures that will allow an electron beam to pass through but will obstruct the passage of ions.

Ion trap.

I/O rack—A chassis that contains I/O modules.

I/O scan—The time required for the PC processor to monitor all inputs and control all outputs. The I/O scan repeats continuously.

IP—Abbreviation for Internet Protocol. The Internet standard protocol that provides a common layer over dissimilar networks, used to move packets among host computers and through gateways if necessary.

I_p —Symbol for the plate current of a vacuum tube.

I-phase carrier—Also called in-phase carrier. A carrier separated in phase by 57° from the color subcarrier.

ips—Abbreviation for inches per second. Used for specifying the speed of a tape traveling past the heads of a tape recorder. The most common speeds are $1\frac{7}{8}$ ips (4.75 cm/s); $3\frac{3}{4}$ ips (9.5 cm/s) and $7\frac{1}{2}$ ips (19 cm/s).

IR—1. Abbreviation for interrogator response. 2. Abbreviation for infrared. 3. Abbreviation for insulation resistance. That resistance offered by an insulation to an impressed dc voltage, tending to produce a leakage current through the insulation.

I^2R —Power in watts expressed in terms of the current (I) and resistance (R).

IRAC—Acronym for Interdepartmental Radio Advisory Committee. It is composed of representatives of eleven government agencies: The FCC; Army; Navy; Air Force; Maritime Commission; and the Treasury, State, Commerce, Agriculture, Interior, and Justice Departments.

IR compensation—A control device that compensates for voltage drop due to current flow.

IR drop—1. The voltage produced across a resistance (R) when there is a current (I) through the resistor. 2. The voltage drop that exists across a resistance when a current is flowing through it.

IRE—Abbreviation for Institute of Radio Engineers, an organization now merged with AIEE. See IEEE.

IREd—An infrared-emitting diode that emits photons in the infrared spectrum when forward biased. See also light-emitting diode.

i region—Abbreviation for intrinsic region. In silicon, a pure region of the group IV element (i.e., having neither excess holes or excess electrons, and therefore having very high resistivity).

IRG—Abbreviation for interrecord gap. 1. Erased area between records that allows stop/start and speed standardization when writing or reading data blocks on magnetic tape. 2. The space between records on magnetic tape caused by delays involved in starting and stopping the tape motion. This gap is used to signal that the end of a record has been reached.

iridescence—The rainbow exhibition of colors in a body, usually caused by interference of light of different wavelengths reflected from superficial layers in the surface of a material.

iris—Also called diaphragm. 1. In a waveguide, a conducting plate (or plates) that is very thin (compared with the wavelength) and occupies part of the cross section of a waveguide. When only a single mode can be supported in the waveguide, an iris appears substantially as a shunt admittance. 2. An adjustable aperture built into a camera lens to permit control of the amount of light passing through the lens.

iris diaphragm—A simple mechanism used to vary the diameter of an aperture. Consists of a number of thin, arc-shaped, metal blades that surround the aperture, each blade having a lower stud at one end and an upper stud at the other end. The lower studs fall into holes in a fixed ring surrounding the aperture, while the upper studs are held by radial slots in a rotatable control ring. Iris openings are measured in f-stops.

I^2R loss—The power lost in transformers, generators, connecting wires, and other parts of a circuit because of the current I through the resistance R of the conductors.

iron constantan—A combination of metals used in thermocouples, thermocouple wires, and thermocouple lead wires. Constantan is an alloy of copper, nickel, manganese, and iron. The iron wire is the positive, the constantan the negative wire.

iron-core coil—A coil in which iron forms part or all of the magnetic circuit, linking its winding. In a choke coil, the core is usually built up of laminations of sheet iron.

iron-core transformer—A transformer in which iron forms part or all of the magnetic circuit, linking the transformer windings.

ironless rotor motor—A motor that has a stationary permanent magnet located in the center of the rotor. The housing is made of soft steel and provides a return path for magnetic flux. Rotor coils are wound on a non-magnetic cage. The rotating member consists only of the hollow cage, the winding shaft, and commutator. Advantages include the elimination of cogging, lower starting voltages, and smoother starting and running. The motors are lightweight, hence inertia is low, providing a high torque-to-inertia ratio and high acceleration. The main disadvantage is that the complex construction is more expensive.

iron loss—See core loss.

iron-vane instrument—An indicating instrument whose operating portion consists of two iron bars, one fixed, one pivoted, placed parallel to each other inside a signal coil. Current through the coil magnetizes the bars in the same direction, and they repel each other, causing the pointer to pivot against the force of a hairspring. A damping vane may be used to slow the movement of the

pointer. Deflection is the same for ac or dc; the meter does not have polarity. The instrument has a nonlinear scale, and readings below $1/5$ scale are extremely difficult to make. Because of inductance effects, use of this type of meter is limited to power-line frequencies.

Iron-vane instrument.

irradiance—The incident radiated power per unit area of a surface; the radiometric counterpart of illumination, usually expressed in watts per square centimeter.

irradiation—1. The application of X-rays, radium rays, or other radiation. 2. The amount of radiant energy per unit area received during a given time interval. This term is used in radiological therapy as well as in describing accidental exposure to radiation. It also can be used to denote radiant energy that ultimately passes through the skin to supply power to implanted electronic devices. 3. The exposure of a material to high-energy emissions. In insulations, done for the purpose of favorably altering the molecular structure.

irregularity—A change from normal.

ISA—Abbreviation for Industry Standard Architecture. The original bus architecture developed by IBM for its AT computer and opened up for use by other manufacturers.

I-scan—A radar display in which a target appears as a complete circle when the radar antenna is correctly pointed at it, the radius of the circle being proportional to the target distance.

I-scope—See I-scan.

ISDN—Abbreviation for integrated services digital network. 1. A digital telephone service network that allows transmission of data, voice, and images over one phone line simultaneously. It can provide speeds of roughly 128,000 bits per second over regular phone lines. In practice, most users are limited to 56,000 or 64,000 bits per second. 2. Telephone technology that provides digital access to voice and data network services for sending speech, data, and video across one line simultaneously.

ISHM—The International Society of Hybrid Microelectronics.

I signal—Also called the fine-chrominance primary. 1. A signal formed by the combination of $+0.74$ of an R - Y signal and -0.27 of a B - Y signal. One of the two signals used to modulate the chrominance subcarrier, the other being the Q signal. 2. Also known as the in-phase signal. The color sidebands produced by modulating the color subcarrier at a phase 57° removed from the burst reference phase. This signal is capable of reproducing the range of colors from orange to cyan (bluish-green).

ISM equipment—A Federal Communications Commission designation for industrial, scientific, and medical equipment.

isobar—1. On meteorological maps, a line denoting places having the same atmospheric pressure at a given time. 2. One of a group of atoms or elements having the same atomic weights but different atomic numbers.

isochromatic—Having the same color, as with the lines of the same tint in the interference figure of anisotropic crystals.

isochrone—On a map or chart, a line joining points associated with a constant time difference in the reception of radio signals.

isochrone determination—A radio location in which a position line is determined by the difference in transit times of signals along two paths.

isochronous—1. Equal in length of time. 2. Occurring at equal intervals of time. 3. Describes modems, terminals, and transmissions in which all bits are of equal duration. There are no start or stop bits as in asynchronous transmissions, and no clocking signals as in synchronous transmissions.

isochronous circuits—Circuits having the same resonant frequency.

isochronous distortion—A measure of a modem's dynamic operation.

isochronous multiplexer—A multiplexer that can interleave two time-independent data streams into one higher-speed stream independent of the master timing control required by a synchronous multiplexer.

isoclinic line—See aclinic line.

isodynamic lines—On a magnetic map, lines passing through points of equal strength of the earth's magnetic field.

isoelectric—Uniformly electric throughout or having the same electric potential, and therefore producing no current.

isoelectronic—Pertaining to atoms having the same number of electrons outside the nucleus of the atom.

isolated—Utterly cut off; refers to that condition in which a conductor, circuit, or device is not only insulated from another (or others), but the two are mutually unable to engender current, emf, or magnetic flux in each other. As commonly used, insulation is associated predominantly with direct current, whereas isolation implies additionally a bulwark against ac fields.

isolated amplifier—A differential amplifier in which the input-signal lines are conductively isolated from the output-signal lines and chassis ground.

isolated I/O module—A module that has each input or output electrically isolated from every other input or output on that module, i.e., each input or output has a separate return wire.

isolating diode—A diode that passes signals in one direction through a circuit but blocks signals and voltages in the opposite direction.

isolating switch—A switch intended for isolating an electric circuit from the source of power. It has no interrupting rating and is intended to be operated only after the circuit has been opened by some other means.

isolation—1. Electrical or acoustical separation between two locations. 2. The technique for producing a high electrical resistance between an integrated-circuit component and the substrate in which it is formed. 3. A reduction in the ability of a system to respond to an excitation or to generate an excitation. 4. A method for implementing electrical independence of devices integrated on the same integrated circuit.

isolation amplifier—Also called buffer amplifier. 1. An amplifier that is used to minimize the interaction

between the circuitry which precedes and that which follows. 2. An amplifier designed to have a galvanic discontinuity between its input and output pins. This discontinuity (called an isolation barrier) must have high breakdown voltage, low dc leakage (high barrier resistance), and low ac leakage (low barrier capacitance). Three-port isolation amplifiers have an additional isolation barrier between the power-supply connection and the signal connections that allows the user to connect power in common with either the amplifier's input or its output. Isolation amplifiers generally serve the following functions not achievable with operational or instrumentation amps: sensing small signals in the presence of very high (10 volts) or unknown common-mode voltages, protecting patients undergoing medical monitoring or diagnostic measurements, and completely breaking ground loops. The isolation amplifier, as well as offering isolation, increases accuracy because of its floating input. In contrast to the instrumentation amplifier, it not only eliminates ground loop errors but further reduces the total system error, because its isolation-mode rejection ratio is generally one or two orders of magnitude higher than the common-mode rejection of an instrumentation amplifier. 3. An amplifier with input circuitry and output circuitry designed to eliminate the effects of changes made at either on the other. 4. An amplifier that has an input circuit that is galvanically (no ohmic connection) isolated from the output stage and the power-supply terminals. This isolation is provided by magnetic, optical, or mechanical coupling techniques. Isolation amplifiers are used in applications that require accurate and safe measurement of dc and low-frequency signals. 5. A circuit that amplifies a signal without needing a galvanic path between its input and output terminal. The circuit can be used to protect individuals and equipment from high voltages and to break ground loops in measurement systems. The high resistance and low capacitance of the isolation region permit little current leakage across its barrier and it withstands a specified high voltage without breakdowns or arcs.

isolation barrier — See isolation amplifier.

isolation diffusion — 1. A technique for separation of the individual components within a monolithic silicon structure; p diffused isolation zones are used to form pn junctions that act as reverse-biased diodes. The transistors are double diffused; that is, they are processed by two diffusion steps after the isolation diffusion. 2. In monolithic integrated circuit technology, the diffusion step that generates back-to-back junctions to isolate active devices from one another.

isolation network — A network inserted into a circuit or transmission line to prevent interaction between circuits on each side of the insertion point.

isolation transformer — A transformer designed to provide magnetic coupling (flux coupling) between one or more pairs of isolated circuits, without introducing significant coupling of any other kind between them — i.e., without introducing either significant conductive (ohmic) or significant electrostatic (capacitive) coupling.

isolator — 1. A device that permits microwave energy to pass in one direction while providing high isolation to reflected energy in the reverse direction. Used primarily at the input of communications-band microwave amplifiers to provide good reverse isolation and minimize VSWR. Consists of microwave circulator with one port (port 3) terminated in the characteristic impedance. 2. A device that acts as a one-way valve for microwave signals to prevent stray receiver signals from leaking out past the LNA onto the antenna. 3. A device that allows the transmission of signals in one direction while blocking or attenuating them in the other.

isolator ferrite — A microwave device that allows rf energy to pass through in one direction with very little loss but that absorbs rf power in the other direction.

isolith — An integrated circuit of components formed on a single silicon slice, but with the various components interconnected by beam leads and with circuit parts isolated by removal of the silicon between them.

isomer — One of two or more substances composed of molecules having the same kinds of atoms in the same proportions but arranged differently. Hence, the physical and chemical properties are different.

isoplanar — A bipolar fabrication process that replaces conventional planar p+ isolation diffusion with an insulating oxide to provide isolation between active elements of a silicon integrated circuit. Circuit elements can be fabricated in less space than conventional isolation techniques with improved speed and power performance.

isopulse system — In adaptive communications, a pulse coding system in which special inserted pulses indicate the number of information pulses that are transmitted.

isostatic — Being subjected to equal pressure from every side.

isothermal region — The stratosphere considered as a region of uniform temperature.

isotones — A group of atoms whose nuclei have the same number of neutrons.

isotope — A species of matter whose atoms contain the same number of protons as some other species, but a different number of neutrons. The atomic numbers of isotopes are identical, but the mass numbers (atomic weights) differ. See radioisotope.

isotropic — 1. Having properties with the same values along axes in all directions. 2. Term applied to substances having certain properties that are manifest in every direction, e.g., electrical conductivity in metals. 3. The ability to react the same regardless of direction of measurement. Isotropic materials will react consistently even if stress is applied in different directions. Stress/strength ratio is uniform throughout material.

isotropic antenna — Also called unipole. A hypothetical antenna radiating or receiving equally in all directions. A pulsating sphere is a unipole for sound waves. In the case of electromagnetic waves, unipoles do not exist physically, but represent convenient reference antennas for expressing directive properties of actual antennas.

isotropic gain of an antenna — See absolute gain of an antenna.

isotropic magnet — A magnetic material having no preferred axis of magnetic characteristics.

isotropic material — 1. A material having the same magnetic characteristics along any axis. 2. A substance whose properties are similar when tested in any direction.

isotropic radiator — A radiator that sends out equal amounts of energy in all directions.

ISP — Abbreviation for Internet service provider. A general term for any company that provides a connection to the Internet for individuals or businesses.

ISV — Abbreviation for instantaneous speed variations. Short-term speed changes resulting from nonuniform capstan speed, tension changes caused by start/stop accelerations, and longitudinal vibrations that are caused by a magnetic tape's sliding over the heads and tape guides.

ITDM — Abbreviation for intelligent time-division multiplexer. Also called a statistical multiplexer. A multiplexer that assigns time slots on demand rather than on a fixed subchannel-scanning basis.

item — 1. A general term denoting one of a number of similar units, assemblies, objects, etc. 2. Any unique manufactured or purchased part or assembly, that is, end product, assembly, subassembly, component, or raw material.

iterations per second—The number of approximations per second in iterative division in a computer; the number of times a cycle of operation can be repeated in one second.

iterative—1. Recurring an infinite number of times. 2. Characteristic of a network with an infinite number of identical sections, or of the impedance looking into such a network.

iterative array—In a computer, a large number of identical, interconnected processing modules used, with appropriate driver and control circuits, to perform simultaneous parallel operations.

iterative division—In computers, a method of performing division by use of addition, subtraction, and multiplication operations. A quotient of specified precision is obtained by a series of progressively closer approximations.

iterative filter—A four-terminal filter that provides iterative impedance.

iterative impedance—1. An impedance that, when connected to one pair of terminals of a four-terminal transducer, causes the same value of impedance to appear between the other two terminals. The iterative impedance of a uniform transmission line is equal to the characteristic impedance of the line. In a symmetrical four-terminal

transducer, the iterative impedances for the two pairs of terminals are equal and the same as the image impedances and the characteristic impedance. 2. The impedance that will terminate the output of a line or network such that the impedance then measured at the input of the line or network will be equal to the (iterative) terminating impedance.

iterative process—The calculating of a desired result by means of a repeating cycle of operations that comes closer and closer to the desired result.

iterative routine—A computer routine composed of repetitive computations, so that the output of every step becomes the input of the succeeding step.

ITU—Abbreviation for International Telecommunication Union.

ITV—Abbreviation for industrial television.

i-type—Intrinsic semiconductor.

i-type semiconductor material—A semiconductor material in which the electron and hole densities are effectively equal under conditions of thermal equilibrium.

IVR—Abbreviation for integrated voltage regulator.

IWW—Abbreviation for intermittent windshield wiper (General Motors, Ford Motor, and Chrysler Corp.). In an automobile, electronic control of the windshield wiper motor to vary the time interval between wipes.

J

J—Letter symbol for joule.

jack—1. A socket to which the wires of a circuit are connected at one end, and into which a plug is inserted at the other end. 2. A type of two-way, or more, concentric contact socket for carrying audio signals. 3. A receptacle into which a mating connector may be plugged. 4. The receptacle that accepts a plug, specifically a phone plug. 5. A plug-in type terminal widely used in electronic apparatus for temporary connections or those requiring frequent connections and disconnections. A connection is made to a jack simply by plugging a probe or plug attached to a flexible insulated wire or cable into the jack. 6. Receptacle for a plug connector leading to the input or output circuit of a tape recorder or other piece of equipment. A jack matches a specific plug.

jack bay—Also called patch bay. A panel containing a number of signal jacks (usually standard phone jacks or mini phone jacks), commonly used in studio recording consoles and in equipment racks to provide flexibility in rerouting signals (beyond that provided by normal switches or controls). The jack bay also offers convenience when temporarily connecting certain equipment to a system, or troubleshooting and aligning equipment.

jacket—1. Pertaining to wire and cable, the outer sheath that protects against environment and may also provide additional insulation. 2. An outer, nonmetallic, protective covering applied over an insulated wire or cable.

jack panel—An assembly composed of a number of jacks mounted on a board or panel.

jackscrew—A screw attached to one half of a two-piece, multiple-contact connector and used to draw both halves together and to separate them.

jaff—Slang for the combination of electronic and chaff jamming.

jag—In facsimile, distortion caused in the received copy by a momentary lapse in synchronism between the scanner and recorder.

jaggies—Irregular edges on something that should look smooth, a byproduct of the method of searching a scene and of too coarse a bit map.

jam—1. In punch-card machines, a condition in the card feed that interferes with the normal travel of the punch cards through the machine. 2. To interfere electronically with the reception of radio signals.

jam input—The presetting or loading of a counter, using inputs provided for the purpose. Also, the establishment of a desired logic state or logic line by the direct application of the appropriate voltage level to the line, regardless of the outputs of other devices connected to it.

jammer—An electronic device for intentionally introducing unwanted signals into radar sets to render them ineffective.

jammer band—The radio-frequency band where the jammer output is concentrated. It is usually the band

between the points where the intensity is 3 dB down from maximum.

jammer finder—Also called burnthrough. Radar that attempts to obtain the range of the target by training a highly directional pencil beam on a jamming source.

jammers tracked by azimuth crossings—Semi-automatic strobe processing and tracking that permits automatic detection and tracking on the basis of azimuth information obtained from the jamming signals emanating from an airborne vehicle.

jamming—Also called active electronic countermeasures. 1. The intentional transmission of radio signals in order to interfere with the reception of signals from another station. 2. Interference with hostile radio or radar signals for the purpose of deceiving or confusing the operator. It may be accomplished by saturating a receiver with sufficient noise to prevent detection and location of a target, or by deceiving the operator with intentionally misleading signals or false echoes without his knowing that such signals are present. 3. The deliberate radiation, reradiation, or reflection of electromagnetic energy to impair the use of electronic devices, equipment, or systems by the enemy. Equipment may consist of rudimentary cw or noise transmitters, broadband transmitters, or complex systems that generate deceptive signals.

jamming effectiveness—The jamming-to-signal ratio, that is, the percentage of information incorrectly received in a test message.

JAN specification—Joint Army-Navy specification. The forerunner of present military specifications; generally superseded by the designation MIL.

J-antenna—A half-wave antenna fed at one end by a parallel-wire, quarter-wave section having the configuration of a J.

Java—A platform-independent programming language invented by Sun Microsystems that is specifically designed for writing programs that can be safely downloaded to a computer through the Internet and immediately run without fear of viruses or other harm to the computer or to files. Using small Java programs (called applets), web pages can include functions such as animations, calculators, and other fancy tricks.

J-carrier system—A broadband carrier system that provides 12 telephone channels and utilizes frequencies up to about 140 kilohertz by means of four-wire transmission on a single open-wire pair.

J-display—Also called J-scan. In radar, a modified A-display in which the time base is a circle and the target signal appears as a radial deflection from it.

JEDEC—Acronym for Joint Electron Device Engineering Council. An industry-sponsored organization whose function is to provide a means of standardization for the industry. This encompasses numbering systems, testing methods and techniques, specifications uniformity,

and similar attempts on the part of the component manufacturers to assist the users of electronic components. In addition, JEDEC attempts to establish a code of ethics for the industry and to offer a set of standards for nonmilitary parts.

JETEC— Acronym for Joint Electron Tube Engineering Council.

jewel bearing— A natural or synthetic jewel, usually sapphire, used as a bearing for a pivot or other moving parts of a delicate instrument.

jezebel— A system for the detection and classification of submarines.

JFET— Abbreviation for junction field-effect transistor. A semiconductor device that operates by altering the conductivity of a region of the semiconductor (the channel) between two contacts (source and drain) by application of a voltage to a third terminal (gate). The current flow between source and drain is controlled by the gate voltage. In a JFET device, the gate voltage is applied to the channel across a pn junction, in contrast to its application across an insulator in a conventional MOSFET. JFETs are of two types: p channel and n channel, depending on whether the channel is n type or p type.

JHG— Abbreviation for Joule heat gradient.

jitter— 1. Instability of a signal in either its amplitude or its phase, or both, due to mechanical disturbances or to changes in supply voltage, component characteristics, etc. 2. In relation to cathode-ray tube displays, error in the signal amplitude, phase, or both that results in small, rapid aberrations in size or position of the image. 3. Error of synchronization between a facsimile's transmitter and receiver characterized by a raggedness in the copy. 4. An aberration of a repetitive display, indicating instability of the signal or of the oscilloscope. May be random or periodic, and is usually associated with the time axis. 5. A loss of synchronization caused by electrical or mechanical malfunctions. 6. Type of analog-communication-line distortion caused by a signal's variation from its reference timing position, which can cause data-transmission errors, particularly at high speeds. This variation can be in amplitude, time, frequency or phase. *See* flicker, 3; fortuitous telegraph distortion.

jittered pulse recurrence frequency— The random variation of the pulse-repetition period. Provides a discrimination capability against repeater-type jammers.

J-K flip-flop— A flip-flop with two conditioning inputs (J and K) and one clock input. If both conditioning inputs are disabled prior to a clock pulse, the flip-flop does not change condition when a clock pulse occurs. If the J input is enabled and the K input is disabled, the flip-flop will assume the 1 condition upon arrival of a clock pulse. If the K input is enabled and the J input is disabled, the flip-flop will assume the 0 condition when a clock pulse arrives. If both the J and K inputs are enabled prior to the arrival of a clock pulse, the flip-flop will complement, or assume the opposite state, when the clock pulse occurs. The J-K flip-flop is a refinement of the R-S flip-flop with the advantage that it has a determinate state when signals

appear on both input terminals; it changes state when all inputs are activated. J and K have no particular meaning, but were selected to avoid conflict with other commonly used symbols.

J-K flip-flop.

job— 1. A group of tasks specified as a unit of work for a computer. Usually by extension, a job includes all necessary programs, linkages, files, and instructions for the operating system. 2. In a computer, a collection of tasks, grouped and run together in order to perform a specific function.

job control language— A special computer command language designed for use in batch systems to inform the systems software and computer operator of unique requirements for the running of a computer program.

job library— A related series of user-identified, partitioned data sets that serve as the primary source of load modules for a given job.

job statement— A control statement that identifies the start of a series of job control statements for a single job.

job step— The carrying out of a computer program explicitly identified by a job control statement. The execution of several job steps may be specified by a job.

jogging— Also called inching. Quick and repeated opening and closing of a motor starting circuit to produce slight movements of the motor.

Johnson counter— Also called Mobius counter or twisted-ring counter. A counter composed of an N -stage shift register with the complement of the last stage returned to the input. It normally has $2N$ states through which it cycles. It has the distinguishing characteristic that only one stage changes state at each count. *See* ring counter, 2.

Johnson noise— Also called thermal noise. 1. The noise generated by any resistor at a temperature above absolute zero. It is proportionate to the absolute temperature and the bandwidth according to the following formula:

$$N = KTB$$

where

N is the noise power in watts

K is Boltzmann's constant, or 1.38047×10^{-23}

T is the absolute temperature in kelvins

B is the bandwidth in hertz

2. A frying or sizzling sound produced by thermal agitation voltages generated in amplifier circuits. It usually occurs in the input circuit (or front end) of an amplifier. Discovered by J. B. Johnson in the late 1920s, this thermal noise may be generated by a resistor at a temperature above absolute zero. It is random noise engendered by thermal agitation.

joined actuator— A multiple breaker such that when one pole trips, all trip, but whereas the faulted pole

is tripfree, the other poles may be kept maintained by a restraining actuator.

joint—A connection between two or more conductors, or the connecting point of two conductors.

joint circuit—A communication link in which there is participation by the elements of more than one service, through control, operations, management, etc.

joint communications—The common use of communication facilities by two or more services of the same country.

Joint electron device Engineering Council—See JEDEC.

Joint electron tube Engineering Council—See JETEC.

joint pole—Pole used in common by two or more utility companies.

joint use—The simultaneous use of pole, line, or plant facilities by two or more kinds of utilities.

Jones plug—A type of polarized connector designed in the form of a receptacle and having several contacts.

Josephson effect—1. The phenomenon described by Brian Josephson to explain the action of currents through and voltages across hairlike gaps in superconductors. On the basis of theoretical considerations, it is predicted that if two superconductors would be brought close enough together, a current could be made to flow across the gap between them. Under certain conditions, a voltage appears across the gap, and high-frequency radiation emanates from it. This predicted radiation would have a frequency precisely equal to $2eV/h$, where V is the measured voltage across the gap. 2. Characteristic of radiation detectors that produce energy that is similar to the energy of superconductive gaps when interacting with photons.

joule—1. The work done by a force of 1 newton acting through a distance of 1 meter. The joule is the unit of work and energy in the mksa system. 2. The energy required to transport 1 coulomb between two points having a potential difference of 1 volt. The joule is 10^7 ergs. The kilowatt-hour is 3.6×10^6 joules. 3. A unit of energy of work $CV^2/2$ equal to 1 wattsecond. Energy stored in a capacitor is equal to $CV^2/2$ joules or wattseconds, where C is capacitance in farads and V is voltage in volts at the capacitor's terminals. The letter symbol for joule is J .

Joule effect—In a circuit, electrical energy is converted into heat by an amount equal to I^2R . Half of this heat flows to the hot junction and the other half to the cold junction.

Joule heat—The thermal energy produced as a result of the Joule effect.

Joule heat gradient—Abbreviated JHG. The rate at which the thermal heat produced by the Joule effect increases or decreases.

Joule's law of electric heating—The amount of heat produced in a conductor is proportional to the resistance of the conductor, the square of the current, and the time.

joystick—1. A control device consisting of a handle with freedom of motion in all directions of a plane, connected to potentiometers or other control devices through suitable linkage permitting natural human input of positioning or other information. The term is derived from the joystick of aircraft. 2. A data-entry device used to manually enter coordinate values in special X-, Y-, and Z-input registers. The device consists of a vertically mounted stick or column that can be moved and twisted. When it is moved backward or forward or sideways, coordinate values are stored in the X- and Y-input registers. The Z-input register is varied whenever the

joystick is twisted clockwise and counterclockwise. These registers must be scanned by the host computer since joysticks normally do not generate interrupts when they are activated. Usually the joystick is used to move a cursor and/or tracking symbol on the face of the CRT screen. Used mainly for computer games. 3. A type of four-channel pan potentiometer that has a shaft with a handle that can be moved forward and back, left and right, or anywhere in between to direct a single input signal to any of four output channels.

J-scan—See J-display.

J-scope—Also called class J oscilloscope. A cathode-ray oscilloscope that presents a J-display.

J/S ratio—A ratio, normally expressed in dB, of the total interference power to the signal-carrier power in the transmission medium at the receiver.

juice—Slang for electric current.

jump—1. To cause the next instruction to be selected from a specific storage location in a computer. 2. A departure from the normal one-step incrementing of the program counter. By forcing a new value (address) into the program counter, the next instruction can be fetched from an arbitrary location (either further ahead or back). For example, a program jump can be used to go from the main program to a subroutine, from a subroutine back to the main program, or from the end of a short routine back to the beginning of the same routine to form a loop. 3. Transfer of program logic flow by bypassing a number of instructions. The jump can be forward over a positive number of bytes or backward by expressing a negative number of bytes. The jump can be conditional on the status of the accumulator or other registers.

jumper—1. A short length of wire used to complete a circuit temporarily or to bypass a circuit. 2. A direct electrical connection, which is not a portion of the conductive pattern, between two points in a printed circuit. 3. An electrical connection between two points on a printed board added after the intended conductive pattern is formed. 4. A short length of cable used to make electric connections within, between, among, and around circuits and their associated equipment. 5. A length of conductor used to establish connections (often temporary) between two points or to provide a path around a break in a circuit. A jumper can interconnect board to connector, board to board, or power supply to black box unit. 6. A direct electrical connection between two points on a film circuit. Jumpers are usually portions of bare or insulated wire mounted on the component side of the substrate. 7. A patch cable or wire used to establish a circuit, often temporarily, for testing or diagnostics.

jumper cable—A short flat cable interconnecting two printed wiring boards or devices.

junction—1. A connection between two or more conductors or two or more sections of a transmission line. 2. A contact between two dissimilar metals or materials (e.g., in a rectifier or thermocouple). 3. A region of transition between p- and n-type semiconductor material. The controllable resultant asymmetrical properties are exploited in semiconductor devices. There are diffused, alloy, grown, and electrochemical junctions. 4. A joining of two different semiconductors or of semiconductor and metal. 5. Optical interface.

junction barrier—The opposition to the diffusion of majority carriers across a pn junction due to the charge of the fixed donor and acceptor ions.

junction battery—A nuclear type of battery in which radioactive strontium 90 irradiates a silicon pn junction.

junction box—1. A box for joining different runs of raceway or cable, plus space for connecting and branching the enclosed conductors. 2. An enclosed distribution panel

for connecting or branching one or more corresponding electric circuits without the use of permanent splices.

junction capacitance—The total small-signal capacitance between the contacts of an uninstalled semiconductor die.

junction capacitor—A capacitor in which the capacitance is that of a reverse-biased pn junction.

Junction capacitor.

junction diode— 1. A two-terminal device containing a single crystal of semiconducting material that ranges from p type at one terminal to n type at the other. It conducts current more easily in one direction than in the other and is a basic element of the junction transistor. Such a diode is the basic part of an injection laser; the region near the junction acts as a source of emitted light. When fabricated in a suitable geometrical form, the junction diode can be used as a solar cell. 2. A pn junction characterized by slower switching speed and higher operating voltage and temperature than the Schottky diode. The fast recovery version of the junction diode turns off faster than the conventional pn junction diode, usually in hundredths of a nanosecond. 3. A semiconductor diode having the property of conducting current more easily in one direction than the other. This device may be made by diffusion of an impurity into a semiconductor crystal to form a junction. Such diodes are the basic elements of an injection laser. Light is emitted from the area near the junction.

Junction diode assembly.

junction FET—A field-effect transistor having one or more gates that form pn junctions with the channel. See also junction field-effect transistor.

junction field-effect transistor—Abbreviated JFET. 1. A transistor made up of a gate region diffused into a channel region. The gate element is a region of semiconductor material (ordinarily, the substrate) insulated by a pn junction from the channel, which is material of opposite polarity. When a control voltage is applied to the gate, the channel is depleted or enhanced, and the current between source and drain is thereby controlled. There is no current when the channel is pinched off. 2. A field-controlled majority carrier

junction capacitance — justification

device where the conductance in the channel between the source and the drain is modulated by a transverse electric field. The field is controlled by a combination of gate-source bias voltage, V_{GS} , and the net drain-source voltage, V_{DS} .

Junction field-effect transistor.

junction filter—A combination of a high-pass and a low-pass filter that is used to separate frequency bands for transmission over separate paths. For example, junction filters are used to separate voice and carrier frequencies at the junction between open-wire and cable so that the carrier frequencies and voice frequencies can be sent over nonloaded and VF-loaded cable pairs, respectively.

junction-gate field-effect transistor—A field-effect transistor having one or more gate regions that form pn junction(s) with the channel.

junction loss— 1. In telephone circuits, that part of the repetition equivalent that can be assigned to interactive effects originating at trunk terminals. 2. The transmission loss due to the mismatch of impedance between two types of transmission facilities. See repetition equivalent.

junction point—See node, 1.

junction pole—Pole at the end of a transposition section of an open-wire line or the pole common to two adjacent transposition sections.

junction station—A microwave relay station that joins a microwave radio leg or legs to the main, or through, route.

junction transistor—A transistor having three alternate sections of p-type or n-type semiconductor material. See also npn transistor; pnp transistor.

junction transposition—Transposition located at the junction pole between transposition sections of an open-wire line.

junction—In crossbar systems, a circuit extending between frames of a switching unit and terminated in a switching device on each frame.

justification— 1. The act of adjusting, arranging, or shifting digits to the left or right so that they conform to a prescribed pattern. 2. The automatic inserting of blank spaces within text to make the right margin even on a page.

justify—To align data about a particular reference or to produce a text with flush left and right margins (a more printlike appearance).

just-operate value—Also called dropout value. The measured functioning value at which a particular relay operates. *Contrast* just-release value.

just-release value—The measured functioning value at which a particular relay releases.

just scale—A musical scale formed by three consecutive triads (those in which the highest note of one is the lowest note of the other), each having the ratio 4 : 5 : 6 or 10 : 12 : 15.

jute—Cordage fiber (such as hemp) saturated with tar and used as a protective layer over cable.

jute-protected cable—A cable having its sheath covered by a wrapping of tarred jute or other fiber.

K

K—1. Symbol for cathode or dielectric constant. 2. Letter symbol for kelvin or kilo. 3. Abbreviation for luminosity factor. 4. In a calculator, a fixed number (a constant) that can be used repetitively. 4. Symbol for 10^3 . When referring to bits or words, $K = 1024$. A 4 K chip is a 4 K-bit chip. A 4 K memory is a 4 K-word memory (typically 4 K bytes). 5. When referring to memory storage capacity, 2^{10} ; in decimal notation, 1024.

k—Letter symbol for kilo-

kA—Letter symbol for kiloampere.

Ka band—The frequency band from 18 to 31 GHz.

Karnaugh map—A display of a truth table in a way such that reduction (simplification) of a Boolean expression is facilitated. It consists of a rectangular or square array (depending on the number of variables) of "locations" whose coordinates correspond to truth-table inputs.

KB or **Kb**—Abbreviation for kilobyte. 1024 bytes (8192 bits).

K-band—A radio frequency band extending from 11 to 36 GHz and having wavelengths of 2.73 to 0.83 cm.

Kbps—Abbreviation for kilobits per second. A standard measurement of data rate and transmission capacity. One Kbps equals 1024 bits per second.

kc—Abbreviation for kilocycle. Now obsolete. Replaced by kHz.

K-carrier system—A broadband carrier system that provides 12 telephone channels and utilizes frequencies up to about 60 kHz by means of four-wire transmission on cable facilities.

K-display—Also called K-scan. Modification of a type-A scan, used for aiming a double-lobe system in bearing or elevation. The entire range scale is displaced toward the antenna lobe in use. One signal appears as a double deflection from the range and relative scales. The relative amplitudes of these two pips indicate the amount of error in aiming the antenna.

keep-alive anode—An auxiliary electrode that maintains a dc discharge in a mercury-pool tube. It has the disadvantage of reducing the peak inverse voltage rating.

keep-alive circuit—In a tr or anti-tr switch, a circuit for producing residual ionization in order to reduce the time for full ionization when the transmitter fires.

keep-alive voltage—A dc voltage that maintains a small glow discharge within one of the gap electrodes of a tr tube. This allows the tube to ionize more rapidly when the transmitter fires, thus preventing damage to the receiver.

keeper—A magnetic conductor, placed over the ends of a permanent magnet, used to complete the magnet circuit of a permanent magnet to protect it against demagnetizing influences.

Kel-f—Polymonochlorotrifluoroethylene—a plastic used as a high-temperature insulation (-55°C to $+135^{\circ}\text{C}$).

kelvin—Formerly degree Kelvin. A unit of absolute temperature equal to $1/273.16$ of the Kelvin scale temperature of the triple point of water. Letter symbol: K.

Kelvin balance—An instrument for measuring current. This is done by sending a current through a fixed and a movable coil attached to one arm of a balance. The resultant force between the coils is then compared with the force of gravity acting on a known weight at the other end of the balance arm.

Kelvin bridge—Also called a double or Thompson bridge. A seven-arm bridge for comparing the resistances of two 4-terminal resistors or networks. Their adjacent potential terminals are spanned by a pair of auxiliary resistance arms of known ratio, and they are connected in series by a conductor joining their adjacent current terminals.

Kelvin bridge.

Kelvin scale—Also called absolute scale. A temperature scale using the same divisions as the Celsius scale, but with the zero point established at absolute zero (-273°C or -459°F), theoretically the lowest possible temperature (the temperature at which all molecular motion stops).

Kendall effect—A spurious pattern or other distortion in a facsimile record. It is caused by unwanted modulation produced by transmission of a carrier signal. Such modulation appears as a rectified baseband that interferes with the lower sideband of the carrier.

Kennelly-Heaviside layer—See Heaviside layer.

kenoplotron—A diode-triode vacuum tube within one envelope. The anode of the diode also serves as the cathode of the triode.

kenotron—Also called a valve tube. 1. A term used primarily in industrial and X-ray fields for a hot-cathode

vacuum tube. 2. A high-vacuum, high-voltage thermionic diode, used primarily as a high-voltage rectifier.

Keplerian elements (Keps)—A collection of data relating to the position of a satellite in its orbit at any given time. This information is interpreted by satellite tracking programs to predict time and duration of satellite passes and directions in which to point antennas. Named for the 19th-century scientist Johannes Kepler.

keranophone—A radio circuit device for audibly demonstrating the occurrence of distant lightning flashes.

kerf—The slit or channel or “L” cut in a resistor during trimming by a laser beam or abrasive jet.

kernel—1. A line within a current-carrying conductor along which the magnetic intensity due to the current is zero. 2. The most basic portion of an operating system, usually supporting only task synchronization, scheduling, communication, and the most rudimentary of memory allocation capabilities. It implements software processes and furnishes the means of interprocess communication; usually written in assembly language. 3. The central portion of a program, containing the bulk of its calculations, that consumes the most execution time.

Kerr cell—A container filled with a transparent material that, when subjected to a strong electric field, exhibits double refraction. Because the two polarized components of an incident light beam have different phase velocities in the medium, this device can rotate the plane of polarization. When placed between crossed polarizers, the Kerr cell, usually containing nitrobenzene, can act as an extremely high-speed shutter for light beams.

Kerr effect—1. An electro-optical effect in which certain transparent substances become double refracting when subjected to an electric field perpendicular to a beam of light. 2. The conversion of plane into elliptically polarized light when reflected from the polished end of a magnet.

Kettering ignition system—Inductive system commonly used for internal combustion engines. Employs induction coil, breaker contacts, capacitor, and a suitable power supply, such as a battery.

keV—Letter symbol for kiloelectronvolt.

key—1. A hand-operated switching device for switching one or more parts of a circuit. It ordinarily consists of concealed spring contacts and an exposed handle or push button. 2. A projection that slides into a mating slot or groove so as to guide two parts being assembled and assure proper polarization.

keyboard—1. In a calculator, keys for digits 0 through 9, plus additional keys for various functions, such as add, multiply, divide, subtract, clear, memory, etc. 2. That portion of a terminal used to generate the character stream to the computer or other communications device. 3. An array of push-button switches with related functions. Keyboards use standard push-button contact switches, Hall-effect switches, capacitive switches, and many others. Any type of momentary-contact switch suitable in terms of size, current switching capacity, etc., may be used. The electrical signal generated by switch closure is routed to the appropriate circuitry where the action indicated by closure of the keyboard switch is initiated. 4. A series of switches, usually in the form of a typewriter keyboard, that a computer operator uses to communicate with the computer.

keyboard computer—A computer whose input employs a keyboard, e.g., an electric typewriter.

keyboarding—Entering information (to a word processor) via a keyboard.

keyboard-operated transmission—See KOX.

keyboard perforator—A mechanism that punches a paper tape from which messages are automatically transmitted by a transmitter distributor. The keyboard is

similar to that of a typewriter and can be operated by any trained typist after a few hours' instruction. As each key is depressed, the tape is punched with corresponding code symbols.

keyboard send/receive—A combination teletypewriter transmitter and receiver with transmission capability from a keyboard only. See KSR.

key cabinet—A case installed on a customer's premises and providing facilities so that different lines to the control office can be connected to various telephone stations. It has signals that indicate originating calls and busy lines.

key click—A transient signal sometimes produced when the key of a radiotelegraph transmitter is opened or closed. The transient is heard in a speaker or headphone as a click.

key-click filter—Also called a click filter. A filter that attenuates the surges produced each time the keying circuit of a transmitter is opened or closed.

keyed adapter—A device that detects a modulated signal and produces a dc output signal whose amplitude varies in accordance with the modulation. In radio facsimile transmission, it is used to provide the keying signal for a frequency-shift exciter unit.

keyed AGC—Abbreviation for keyed automatic gain control.

keyed automatic gain control—Abbreviated keyed AGC. A television automatic gain control in which the AGC tube is kept cut off except when the peaks of the positive horizontal-sync pulse act on its grid. The AGC voltage is therefore not affected by noise pulses occurring between the sync pulses.

keyed clamp—A clamping circuit in which a control signal determines the time of clamping.

keyed interval—In a periodically keyed transmission system, an interval that starts from a change in state and has a length equal to the shortest time between changes in state.

keyed rainbow generator—A color television test instrument that displays the individual colors of the spectrum, separated by black bars, on the picture tube.

keyed rainbow signal—A 3.563795-MHz (3.56-MHz) continuous sine-wave signal from a color-bar generator that is pulsed on and off. This signal creates a series of different color bars on the screen of the color picture tube. A typical pulse rate (for 10 color bars) is 12 times per 1 horizontal line.

keyer—1. In telegraphy, a device that breaks up the output of a transmitter or other device into the dots and dashes that are used in the code. 2. A radar modulator.

keying—1. The forming of signals, such as those employed in a telegraph transmission, by an abrupt modulation of the output of a director by an alternating-current source (e.g., by interrupting it or by suddenly changing its amplitude, frequency, or some other characteristic). 2. Mechanical arrangement of guide pins and sockets, keying plugs, contacts, bosses, slots, keyways, inserts, or grooves in a connector housing, shell, or insert that allows connectors of the same size and type to be lined up without the danger of making a wrong connection.

keying chirps—Sounds accompanying code signals when the transmitter is unstable and shifts slightly in frequency each time the sending key is closed.

keying frequency—In facsimile, the maximum number of times a second a black-line signal occurs while scanning the subject copy.

keying plug contact—A component that is inserted into a cavity of a connector housing or insert to ensure engagement of identically matched components.

keying wave—Also called marking wave. The emission that takes place in telegraphic communication

while the information portion of the code characters is being transmitted.

keyless ringing—A type of machine ringing on a manual switchboard. Ringing is started automatically when the calling plug is inserted into the jack of the called line.

keypad—Device with a matrix of keys enabling a user to input (usually numeric) information into another device, as in dialing a touch-tone telephone.

key pulse—A telephone signaling system in which numbered keys are depressed instead of a dial being turned.

key pulsing—A switchboard arrangement using a nonlocking keyset for the transmission of pulse signals corresponding to the key depressions.

key-pulsing signal—The signal that indicates a circuit is ready for pulsing, in multifrequency and direct-current key pulsing.

keypunch—A keyboard-operated device that punches holes in punch cards to represent data to be input to a computer by a card reader.

keyshelf—A shelf on which are mounted the keys by means of which the operator of a manual telephone switchboard performs switching of one or more of the switchboard circuits.

key signal—A pseudorandom sequence of two-level pulses used to accomplish enciphering or deciphering processes.

key station—The master station from which a network radio or television program originates.

keystone distortion—The distortion produced when a plane target area not normal to the average direction of the beam is scanned rectilinearly with constant-amplitude sawtooth waves.

Keystone distortion.

keystone shaped—Wider at the top than at the bottom, or vice versa.

keystoning—The keystone-shaped scanning pattern produced when the electron beam in the television camera tube is at an angle with the principal axis of the tube. *See also* keystone shaped.

keyswitch—In an organ, the switch that is closed to allow a tone from the tone generator to sound when a key is depressed.

key telephone—Also called key telephone set. Telephone set having six button keys and used with relay equipment to provide call holding, multiline pickup, signaling, intercommunication, and conference services.

key telephone set—A desk telephone with six (illuminated) push-button keys across the set below the dial. The keys may be connected to hold, pick up a central office line, or pick up an intercom line.

key telephone system—A versatile station switching system located on a customer's premises, consisting of one or more multibutton telephone sets and associated equipment. Permits mutual access and control of a number of central office lines, as well as pickup, hold, signal, and intercommunication capability.

key up—To turn on a repeater by transmitting on its input frequency.

keyway—The mating slot or groove in which a key slides.

keyword—1. Characteristic word in a computer file used to retrieve its contents. 2. A word (with a special meaning) that is recognized by the computer or program.

kHz—Abbreviation for kilohertz. A unit of frequency measurement equivalent to 1000 cycles per second; formerly expressed as kilocycles per second, or kc/s.

kickback—The voltage developed across an inductance by the sudden collapse of the magnetic field when the current through the inductance is cut off.

kickback power supply—*See* flyback power supply.

kick-sorter—British term for pulse-height analyzer.

kidney joint—A flexible joint, or air-gap coupling, located in the waveguide and near the transmitting-receiving position of certain radars.

Kikuchi lines—A series of spectral lines obtained by the scattering of electrons when an electron beam is directed against a crystalline solid. The pattern may be interpreted to yield information on the structure of the crystal and its mechanical perfection.

killer circuit—1. The vacuum tube or tubes and associated circuits in which are generated the blanking pulses used to temporarily disable a radar set. 2. In a transponder, a logic circuit that kills replies to side-lobe interrogations.

killer pulse—*See* suppression pulse.

kilo—A prefix representing 10^3 , or 1000. Letter symbol: k.

kiloampere—1000 amperes. Letter symbol: kA.

kilobaud—Abbreviated kBd. One thousand baud.

kilobit—1024 bits.

kilobyte—1. A standard quantity measurement for disk and diskette storage and semiconductor circuit capacity: 1 kilobyte of memory equals 1024 bytes (8-bit characters) of computer memory. 2. 2^{10} , or 1024, bytes. Commonly thought of as 1000 bytes. Abbreviated K and used as a suffix to describe memory size.

kilocycle (kc)—1000 cycles. Generally interpreted as meaning 1000 cycles per second. Obsolete term; replaced by kilohertz (kHz).

kiloelectronvolt—1000 electron volts. The energy acquired by an electron that has been accelerated through a voltage difference of 1000 volts. Letter symbol: keV.

kilogauss—1000 gauss.

kilogram—Unit of mass. The mass of a particular cylinder of platinum-iridium alloy, called the international prototype kilogram, that is preserved in a vault at Sevres, France, by the International Bureau of Weights and Measures. Letter symbol: kg.

kilohertz—1000 hertz. Letter symbol: kHz.

kilohm—1000 ohms. Abbreviated k or kohm.

kilohmmeter—A meter designed for measuring resistance in kilohms.

kilomega (kM)—Obsolete prefix for giga- (G), representing 10^9 or 1,000,000,000.

kilomegacycle—Now called gigahertz. One billion cycles per second.

kilometer—One thousand meters, or approximately 3280 feet.

kilometric waves—British term for electromagnetic waves between 1000 and 10,000 meters in length.

kilosecond—1000 seconds.

kilovar—One reactive kilovoltampere, or 1000 reactive voltamperes. Letter symbol: kvar.

kilovar-hour—1000 reactive volt-amperehours.

kilovolt—1000 volts. Letter symbol: kV.

Klydonograph gradient recorder.

kilovoltampere — 1000 voltamperes. Letter symbol: kVA.

kilovoltmeter — A voltmeter that reads thousands of volts.

kilowatt — 1000 watts. Letter symbol: kW.

kilowatthour — The equivalent energy supplied by a power of 1000 watts for 1 hour. Letter symbol: kWh.

kine — Slang term for kinescope recording.

kine-klydonograph — An instrument that records the current-time characteristics of a lightning stroke. The instrument records a series of Lichtenberg figures in a manner similar to that of the field gradient recorder.

kinescope — 1. A cathode-ray tube that serves as a picture tube in a television receiver. The signal representing the picture intensity is transmitted to the electron gun grid so that the beam intensity varies with the intensity of the original scene. Deflecting voltages sweep the beam horizontally and vertically until it is synchronized with the scanning of the camera tube. The electron beam then strikes the fluorescent end screen of the tube and the scene is reproduced. 2. A film recording made from a television program on a picture tube and used as a permanent record or for subsequent rebroadcasting.

Kinescope, 1.

kinescope gun — The electron gun in the kinescope.

kinescope recorder — A camera that photographs television images directly from the picture tube onto motion-picture film.

kinetic energy — Energy that a system possesses by virtue of its motion.

Kirchhoff's laws — 1. The current flowing to a given point in a circuit is equal to the current flowing away from that point. 2. The algebraic sum of the voltage drops in

any closed path in a circuit is equal to the algebraic sum of the electromotive forces in that path. (Laws 1 and 2 are also called laws of electric networks.) 3. At a given temperature, the emissive power of a body is the same as its radiation-absorbing power for all surfaces.

kit — A prepared package of parts with instructions for assembly and/or wiring a component or chassis (also a small accessory item).

klydonograph — A field gradient recording instrument that registers voltages on photographic film in the form of Lichtenberg figures.

klystron — An electron tube used as an oscillator or amplifier at ultrahigh frequencies. The electron beam is velocity modulated (periodically bunched) to accomplish the desired results.

Klystron.

klystron control grid — An electrode that controls the emission, or beam current, of a klystron or other velocity-modulated tube.

klystron frequency multiplier—A two-cavity klystron that has the output cavity tuned to a multiple of the fundamental frequency.

klystron generator—A klystron tube used as a generator. Its cavity feeds energy directly into a waveguide.

klystron oscillator—An oscillator employing a klystron tube to generate radio-frequency power.

klystron repeater—A klystron tube operated as an amplifier and inserted directly into a waveguide in such a way that incoming waves velocity-modulate the electron stream emitted from a heated cathode. A second cavity converts the energy of the electron clusters into waves of a much higher amplitude and feeds them into the outgoing guide.

kM—Abbreviation for kilomega (an obsolete term). Replaced by giga.

kMc—Abbreviation for kilomegacycle. Now replaced by gigahertz.

knee—1. An abrupt change in direction between two relatively straight segments of a curve, such as the region of a magnetization curve near saturation or the top bend of a vacuum-tube characteristic curve. 2. A section between two comparatively straight segments of a curve in which the magnitude of curvature, although of the same sign, is relatively high. 3. The region of maximum curvature.

knife-edge diffraction—In radio-wave propagation, an effect by which the atmospheric attenuation of a signal is reduced when the signal is diffracted as it passes over a sharp obstacle such as a mountain ridge.

knife-edge pointer (of a meter)—A pointer whose end is flattened and turned edgewise so the smallest dimension or edge is seen. Usually used with mirror-backed scales to eliminate parallax and increase the accuracy of reading.

knife switch—1. A form of air switch in which a moving element is sandwiched between two contact clips. The moving element is usually a hinged blade; when it is not, it is removable. 2. A form of switch in which the moving element, usually a hinged blade, enters or embraces stationary contact clips.

knob—A round, polygonal, or pointer-shaped part that is fastened to one end of a control shaft so that the shaft can be turned more easily. The knob sometimes indicates the degree of rotation also.

knocker—A term used with some fire-control radars to indicate a subassembly comprising synchronizing and triggering circuits. It drives the rf pulse-generating equipment in the transmitter and also synchronizes the cycle of operation with the transmitted pulse in range units and indicators.

knockout—A removable portion in the side of a box or cabinet. During installation it can be readily taken out

klystron frequency multiplier — kymograph

with a hammer, screwdriver, or pliers so the raceway, cables, or fittings can be attached.

knot—One nautical mile (6,080.20 feet, 1852 meters, or 1.15 statute miles) per hour.

Koorman antenna—A vertical array of horizontal full-wave dipoles that are driven by transposed two-conductor line and backed by a parasitic reflecting curtain or horizontal dipoles.

Kovar—An iron-nickel-cobalt alloy with a coefficient of expansion similar to that of glass and silicon and thermal characteristics similar to those of alumina. It is used as a material for headers and in glass-to-metal seals. Kovar/glass packages are used extensively in hybrid construction to preserve hermetic sealing.

KOX—Acronym for keyboard-operated transmission. A station equipped with a KOX system can turn on the transmitter and turn off the receiver simply by typing on the station's keyboard. When the operator ceases typing, the transmitter automatically turns off, and the receiver turns on after some preset delay.

kraft paper—Relatively heavy, high-strength sulfate paper used for electrical insulating material. (Capacitor tissue is kraft paper of normal thickness equal to 0.002 inch, or 50 μ m, or less.)

K-scan—See K-display.

K-series—A series of frequencies in the X-ray spectrum of an element.

KSR—Abbreviation for keyboard send-receive unit. A combination transmitter and receiver with transmission capability from the keyboard only (teletypewriter term). Refers to a terminal device (teletype or similar) having only a keyboard for sending and a printer for receiving, i.e., no paper or magnetic tape equipment, but which is useful for conversational time-sharing and inquiry-response applications.

Ku band—1. A band of microwave frequencies between 11 and 13 GHz. 2. Also called K band. A band of frequencies that extends from 11.7 to 12.7 GHz. The band is separated into two portions: 11.7 to 12.2 GHz (fixed satellite services—intended for point-to-point services) and 12.2 to 12.7 GHz (for broadcasting satellite service or DBS). 3. The frequency band from 10.9 to 17 GHz.

kurtosis—The degree of curvature of the peak of a probability curve.

kV—Letter symbol for kilovolt.

kVA—Letter symbol for kilovoltampere.

kvar—Letter symbol for kilovar.

kW—Letter symbol for kilowatt.

kWh—Letter symbol for kilowatt-hour.

kymograph—An instrument for recording wavelike oscillations of varying quantities for medical studies.

L

L—Symbol for coil, lambert, or inductance.

label—1. A code name used to identify or classify a name, term, phrase, or document. 2. One or more characters that serve to identify an item of data. 3. A numerical value or a memory location in the programmable system of a computer. The specific absolute address is not necessary since the intent of the label is a general destination. Labels are a requisite for jump and branch instructions. 4. A number or letter or a name given to a program statement so that the computer can find it later. 5. A name used in source code to identify an instruction or executable statement in computer programs. 6. A block at the beginning or at the end of a volume or file that identifies, characterizes, and/or delimits that volume or file. A label is not considered to be part of a file.

label group—A collection of continuous label sets of the same label type.

labile oscillator—A local oscillator whose frequency is remote controlled by a signal received from a radio or over a wire.

laboratory power supply—A regulated dc source having (a) less than 10-kV output at up to 500 W, (b) output adjustable over a wide range, usually down to zero, (c) regulation on the order of ± 0.01 percent static line and load.

labyrinth—Speaker enclosure with absorbing air chambers at the rear to eliminate acoustic standing waves. A mazelike construction extends the air column. Resonances are tamed by heavy damping material.

labyrinth loudspeaker—Loudspeaker mounted in an acoustic baffle having air chambers designed to prevent acoustic standing waves.

lacing—A network of fine wire surrounding or covering an area to be protected, such as a safe, vault, or glass panel, and connected into a closed-circuit system. The network of wire is concealed by a shield, such as concrete or paneling, in such a manner that an attempt to break through the shield breaks the wire and initiates an alarm.

lacing and harnessing—Also called bundling. A method of grouping wires by securing them in bundles or designated patterns.

lacing cord or twine—Cord used for lacing and tying cable forms, hookup wires, cable ends, cable bundles, and wire harness assemblies. Available in various materials and impregnants.

lacing tape—Flexible, flat, fabric tape for tying harnesses and wire bundles, securing of sleeves and other items, and general lacing and tying applications.

lacquer disc—Also called cellulose-nitrate disc. A mechanical recording disc, usually made of metal, glass, or paper and coated with a lacquer compound often containing cellulose nitrate.

lacquer master—See lacquer original.

lacquer original—Also called lacquer master. An original recording made on a lacquer surface to be used as a master.

lacquer recording—Any recording made on a lacquer medium.

ladder attenuator—A series of symmetrical sections used in signal generators and other devices in which voltages and currents must be reduced in known ratios. They are designed so that the required ratio of voltage loss per section is obtained with image-impedance operation. The impedance between any junction point and common ground in a ladder attenuator is half the image impedance.

Ladder attenuator.

ladder diagram—1. A diagram that shows actual component symbols and the basic wiring configuration of a relay logic circuit (as opposed to a logic diagram). 2. An industry standard for representing control logic relay systems. 3. Electrical engineering technique to schematically illustrate functions in an electrical circuit (relays, switches, timers, etc.) by diagramming them in a vertical sequence resembling a ladder. 4. See contact symbology diagram.

ladder network—Also called series-shunt network. 1. A network composed of H-, L-, T-, or pi networks connected in series. 2. A series of film resistors with values from the highest to the lowest resistor reduced in known ratios.

LAFOT—Coded weather broadcasts issued by the U.S. Weather Bureau for the Great Lakes region. They are broadcast every 6 hours by marine radiotelephone broadcasting stations on their assigned frequencies.

lag—1. The displacement in time, expressed in electrical degrees, between two waves of the same frequency. 2. The time between transmission and reception of a signal. 3. In a television camera tube, the persistence of the electrical-charge image for a time interval equal to a few frames. 4. A time difference between the occurrence of two events.

Lag, 1.

lagged-demand meter—A meter in which there is a characteristic time lag, by either mechanical or thermal means, before maximum demand is indicated.

lagging current—The current flowing in a circuit that is mostly inductive. If the circuit contains only inductance, the current lags the applied voltage by 90° . Because of the characteristics of an inductance, the current does not change direction until after the corresponding voltage does.

lagging load—A predominantly inductive load—i.e., one in which the current lags the voltage.

lag-lead—Also called lead-lag. A circuit whose response includes lag components and their derivatives.

lambda—Greek letter λ , used to designate wavelength measured in meters.

lambda diode—A simple two-terminal device consisting of a pair of complementary depletion-mode junction field-effect transistors that can be fabricated more easily than conventional negative-resistance devices. It can be integrated on a single chip or with bipolar and MOS devices on the same chip. Unlike tunnel diodes, which are limited to a narrow negative-resistance range, lambda diodes can be produced with a wide range of characteristics.

lambda wave—An electromagnetic wave propagated over the surface of a solid that has a thickness comparable to the wavelength of the wave.

lambert—A unit of luminance (photometric brightness) equal to $1/\pi$ candela per square centimeter and, therefore, equal to the uniform luminance of a perfectly diffusing surface emitting or reflecting light at the rate of 1 lumen per square centimeter. The lambert also is the average luminance of any surface emitting or reflecting light at the rate of 1 lumen per square centimeter. For the general case, the average must take account of variation of luminance with angle observation, also of its variation from point to point on the surface considered. Letter symbol: L.

lambertian—A radiance distribution that is uniform in all directions of observation.

Lambert's law of illumination—The illumination of a surface on which the light falls normally from a point source is inversely proportional to the square of the distance of the surface from the source. If the normal to the surface makes an angle with the direction of the rays, the illumination is proportional to the cosine of that angle.

laminar flow—A directed stream of filtered air moved constantly across a clean work station, usually parallel to the workbench surface.

laminate—A product made by bonding together two or more layers of material.

laminated—Made of layers.

laminated contact—A switch contact made up of a number of laminations, each making contact with an opposite conducting surface.

laminated core—An iron core for a coil, transformer, armature, etc. It is built up from laminations to minimize the effect of eddy currents. The sheet iron or steel laminations are insulated from each other by surface oxides or by oxides and varnish.

laminated record—A mechanical recording medium composed of several layers of material (normally a thin face of material on each side of a core).

lamination—A single stamping of sheet material used in building up a laminated object such as the core of a power transformer.

Lamont's law—The permeability of steel at any flux density is proportional to the difference between the saturation value of the flux density and its value at the point in question. This law is only approximately accurate and is not true for the initial part of the magnetization curve.

lamp—1. A generic term for a human-made source of light. By extension, the term is also used to denote sources that radiate in regions of the spectrum adjacent to the visible range. 2. A device for producing light.

lamp bank—An arrangement of incandescent lamps commonly used as a resistance load during electrical tests.

lamp cord—1. A twin conductor, either twisted or parallel, used for connecting floor lamps and other electric appliances to wall outlets. 2. Flexible stranded conductor cord, rubber or plastic insulated, used in wiring of lamps, household fans, and similar appliances. Not subject to hard usage.

lamp holder—A lamp socket.

lamp housing—A device designed to concentrate and direct a light source by enclosing the source in it and using a concave reflector to direct the light through its only opening.

lamp jack—Special electronic electromechanical component having a frame that holds a lamp and has the contact springs and terminals for applying power to the lamp. Used extensively in jack panels and other types of telephone equipment as a visual-indicating signal device.

Lampkin oscillator—A variation of the Hartley oscillator. Its distinguishing feature is that an approximate impedance match is effected between the tank and grid-cathode circuits.

lamp receptacle—A device that supports an electric lamp and connects it to a power line.

LAN—Abbreviation for local area network. 1. A data communications network spanning a limited geographical area, such as an office, an entire building, or industrial park. It provides communication between computers and peripherals. 3. A baseband or broadband interactive bidirectional communication system for voice, video, or data use on a common cable medium. The network uses some type of switching technology and does not use common-carrier circuits, although it may have gateways or bridges to other public or private networks.

land—1. The surface between two adjacent grooves of a recording disc. 2. Also called boss, pad, terminal point, blivet, tab, spot, donut. In a printed circuit board, the conductive area to which components or separate circuits are attached. It usually surrounds a hole through the conductive material and the base material. 3. A portion of a conductive pattern usually, but not exclusively, used for the connection and/or attachment of components. 4. Widened conductor area on the major substrate used as an attachment point for wire bonds or the bonding of chip devices.

Landau damping—The damping of a space-charge wave by electrons moving at the phase velocity of the wave.

landing beacon—The radio transmitter that produces a landing beam for aircraft. *See also* landing beam.

landing beam—A highly directive radio signal projected upward from an airport to guide aircraft in making a landing during poor visibility.

landless hole—A plated-through hole without a land(s).

landline—A telegraph or telephone line passing over land, as opposed to submarine cables.

landline facilities—Domestic communications common-carrier's facilities that are within the continental United States.

landmark beacon—Any beacon other than an airport or airway beacon.

land mobile service—A radio service in which communication is between a base station and land mobile stations or between land mobile stations.

land mobile station—A two-way mobile station that operates solely on land.

land radio positioning station—A station in the radio positioning service, not intended to be operated while in motion.

land return—Radiation reflected from nearby land masses and returned to a radar set as an echo.

lands—Bonding points used in the manufacture of microelectronic circuits.

landscape—In word processing, printing a page horizontally across the width of the paper.

land station—A permanent, or fixed, station.

land transportation radio services—Radio-communication services whose transmitting facilities include fixed, land, or mobile stations, operated by and for the sole use of certain land transportation carriers.

Langevin ion—An electrified particle produced in a gas by an accumulation of ions on dust particles or other nuclei.

Langmuir dark space—The nonluminous region surrounding a negatively charged probe inserted into the positive column of a glow or arc discharge.

language—1. A set of computer symbols, with rules for their combination. They form a code to express information with fewer symbols and rules than there are distinct expressible meanings. 2. A format for computer programs. Ultimately, computers receive their instructions in machine language, binary codes whose meanings are specific to each computer. Machine codes are usually written in hex or octal for easier use by humans. High-level languages, such as BASIC, allow programs to be written in fairly human terms (such as PRINT "NOW IS THE TIME") that are then translated into a sequence of machine codes. 3. A system for representing information and communicating it between people, or between people and machines. 4. A definition of the elements and syntax within which a computer program must be encoded. 5. The means by which people communicate with a computer.

language converter—A data-processing device designed to change one form of data, i.e., microfilm, strip chart, etc., into another (punch card, paper tape, etc.).

language translation—The process performed by an assembler, compiler, or other routine that accepts statements in one language and converts them to equivalent statements in another language.

language translator—A computer system program that translates text written in one language to another language. Assemblers, interpreters, and compilers are examples of language translators.

L-antenna—An antenna consisting of an elevated horizontal wire to which a vertical lead is connected at one end.

lanyard—A device that is attached to certain quick-disconnect connectors and that permits uncoupling and separation of connector halves by a pull on a wire or cable.

lap—1. A rotation plate covered with liquid abrasive, used for grinding quartz crystals. 2. A fire-resistant, untwisted, ribbonlike form of asbestos felt made from

slivers of asbestos fiber blended with cotton or other organic fibers. Used as a wrapping on wire and cable.

LAP—Abbreviation for Link Access Protocol. The data link layer protocol that is used in X.25-based networks in setting up channels between data termination equipment and data communication equipment.

lap computer—A battery-operated computer, small and light enough to be operated on the user's lap.

lap dissolve—In motion pictures or television, simultaneous transition in which one scene is faded down and out while the next scene is faded up and in.

lapel microphone—A microphone worn on the user's clothing.

lap joint—The connecting of two conductors by placing them side by side so that they overlap.

Laplace's law—The strength of the magnetic field at any given point due to any element of a current-carrying conductor is directly proportional to the strength of the current and the projected length of the element, and is inversely proportional to the square of the distance of the element from the point in question.

Laplace transform—A mathematical substitution whose use permits the solution of a certain type of differential equation by algebraic means.

lapping—1. Bringing quartz crystal plates up to their final frequency by moving them over a flat plate over which a liquid abrasive has been poured. 2. Grinding and polishing such products as semiconductor blanks in order to obtain precise thicknesses or extremely smooth, flat, polished surfaces.

laptop—A small portable computer. Sometimes distinguished as larger than a notebook computer, but sometimes also used as a synonym for notebook computer.

lap winding—An armature winding in which opposite ends of each coil are connected to adjoining segments of the commutator so that the windings overlap.

lap wrap—Tape wrapped around an object in an overlapping condition.

large-scale integrated circuit—An integrated circuit that contains 100 gates or more in a single chip, resulting in an increase in the scope of the function performed by a single device.

large-scale integration—Abbreviated LSI. 1. The simultaneous achievement of large-area circuit chips and optimum density of component packaging for the express purpose of cost reduction by maximization of the number of system interconnections made at the chip level. 2. Monolithic integrated circuits of very high density. Such circuits typically have on a single chip the equivalent of about 200 to thousands of simple logic circuits. The term sometimes describes hybrid ICs built with a number of MSI or LSI chips. 3. A classification of ICs by size, applicable to chips containing more than 100 gates or circuits of equivalent complexity. 4. The technology that produces microcircuits with at least 100 active devices on a single chip. Functional blocks that include several op amps and other devices are examples of LSI devices.

large-signal characteristics—The characteristics of an amplifier when rated (full) output signals are produced.

large-signal dc current gain—The dc output current of a transistor with the dc output circuit shorted, divided by the dc input current producing the dc output current.

large-signal power gain—The ratio of the ac output power to the ac input power under specified large-signal conditions. Usually expressed in decibels (dB).

large-signal short-circuit forward-current transfer ratio—In a transistor, the ratio under specified test conditions of a change in output current to the corresponding change in input current.

large-signal voltage gain—The ratio of the output voltage swing of an operational amplifier to the change in input voltage required to drive the output from zero to this voltage.

Larmor orbit—The path of circular motion of a charged particle in a uniform magnetic field. The motion of the particle is unimpeded in the direction of the magnetic field, but motion perpendicular to the direction of the field is always accompanied by a force perpendicular to the direction of motion and the field.

laryngaphone—Also called a throat microphone. A microphone applied to the throat of a speaker to pick up voice vibrations directly. It is very useful in noisy locations because it picks up only the speaker's voice—no outside noises.

LASCR—Abbreviation for light-activated silicon-controlled rectifier. 1. A pnpn device in which incident light performs the function of gate current; three of the four semiconductor regions are available for circuit connections. A photoswitch. 2. A semiconductor device that is triggered into conduction when the light falling on the base-collector photodiode junction exceeds a given threshold level. Operation of the LASCR is similar to the silicon-controlled rectifier, with the major difference being that an external resistance between gate and cathode (in addition to bias voltage and current) determines light sensitivity. A positive electrical signal applied to the gate can be used to trigger the LASCR, as well as to modify the light sensitivity.

Anode characteristic.

LASCR.

LASCS—Abbreviation for light-activated silicon-controlled switch. 1. A device similar to an LASCR, except that all four semiconductor regions are accessible. 2. A semiconductor device that combines the LASCR and the planar silicon photoswitch (PSPS). Having four terminals, the LASCS can be triggered by light positive signals (at the gate terminal) and negative signals (at the anode gate terminal).

laser—1. A device for transforming incoherent light of various frequencies of vibration into a very narrow, intense beam of coherent light. The name is derived from the initial letters of "light amplification by stimulated emission of radiation." In the emission of ordinary light, the molecules or atoms of the source emit their radiation

large-signal voltage gain — laser diode coupler

independently of each other, and consequently there is no definite phase relationship among the vibrations in the resultant beam. The light is incoherent. The laser, by means of an optical resonator, forces the atoms of the material of the resonator to radiate in phase. The emitted radiation is stimulated by the excitation of atoms to a higher energy level by means of energy supplied to the device. In the microwave region, the corresponding device is called a maser, and hence the laser is also known as a light maser. 2. A device for producing light by emission of energy stored in a molecular or atomic system when stimulated by an input signal. 3. A mechanically designed semiconductor junction that will optically pump (amplify light) short pulses of high-energy coherent radiation. 4. A device that produces a coherent monochromatic (single wavelength) collimated beam of concentrated light in which the subatomic particles that constitute the beam, known as photons, travel on a parallel axis. Scientists believe that a beam produced by a 5-megawatt laser would be able to melt objects in space at distances exceeding 5000 miles (8045 km).

Laser.

laser basic mode—The primary or lowest-order fundamental transverse propagation mode for the emitted light wave of a laser, the emitted energy normally having Gaussian (bell-shaped) distribution in space and being in a single beam, with no side lobes.

laser bonding—1. A process that forms a metal-to-metal fastened union, using a laser heat source to join conductors. 2. Effecting a metal-to-metal bond of two conductors by welding the two materials together using a laser beam for a heat source.

laser cavity—An optically resonant and hence mode-selecting low-loss structure in which laser action occurs through the buildup of electromagnetic field intensity upon multiple reflection.

laser diode—Abbreviated LD. A junction diode, consisting of positive and negative carrier regions with a pn transition region (junction), that emits electromagnetic radiation (quanta of energy at optical frequencies) when injected electrons under forward bias recombine with holes in the vicinity of the junction. In certain materials, such as gallium arsenide, there is a high probability of radiative recombination producing emitted light, rather than heat, at a frequency suitable for optical waveguides. Some light is reflected by the polished ends and is trapped to stimulate more emission. See diode laser; injection laser diode.

laser diode coupler—A coupling device that enables the coupling of light energy from a laser diode

(LD) source to an optical fiber or cable at the transmitting end of an optical fiber data link. The coupler may be an optical fiber pigtail epoxied to the LD. Synonym: LD coupler.

Laserdisc—A laser-read optical video disc system that can hold thousands of video images and hours of sound. A 12-inch plastic disc used to store video, audio, and other data for playback on a video disc player and video monitor.

laser Doppler velocimeter—A laser device utilizing either optical heterodyning or scanning interferometry to measure flow velocities by means of the Doppler shift.

laser drill—A system that uses a laser as the source in the evaporation of localized areas as small as 0.00025 cm in diameter of hard materials such as gemstones and tungsten. A pulsed ruby laser is most commonly used in this type of system.

laser dyes—Class of organic dyes that emit coherent radiation over a wide spectral range.

laser fiber-optic transmission system—A system consisting of one or more laser transmitters and associated fiber-optic cables. During normal operation the laser radiation is limited to the cable.

laser head—A module containing the active laser medium, resonant cavity, and other components within one enclosure, not necessarily including a power supply.

laser holographic camera—A camera system that has a laser, usually of the pulsed ruby type, as a light source; holographic optics; a plate; and a plate holder. It is used often in the laboratory or in production areas for analysis and detection. The laser's nanosecond exposure time is most efficient in freezing moving particles in a permanent hologram for convenient analysis.

laser linewidth—In the operation of a laser, the frequency range over which most of the laser beam's energy is distributed.

laser printer—A printer whose images are formed by laser light impinging on a light-sensitive drum like that of a photocopy machine; where the light strikes the drum, it will hold xerographic ink for transfer to a sheet of paper.

laser protective housing—A protective housing for a laser to prevent human exposure to laser radiation in excess of an allowable established or statutory emission limit for the appropriate class. Parts of the housing that can be removed or displayed and not interlocked may be secured in such a way that removal or displacement of the parts requires the use of special tools.

laser pulse length—Also called laser pulse width. The time duration of the burst of electromagnetic energy emitted by a pulsed laser. It is usually measured at the half-power points, i.e., on a plot of pulse power developed versus time, the time interval between the points that are at 0.5 of the peak of the power curve.

laser pulse width—*See* laser pulse length.

laser rangefinder—A portable instrument that measures the distance between itself and its target by determining the amount of time it takes for a pulsed laser beam to travel to the target and be reflected back to the instrument. A telescope is used to aim the beam, and a photomultiplier detects the reflected pulse.

laser ranger—A device similar to conventional radar but using high-intensity light rather than microwaves.

laser soldering—A selective soldering technique employing a programmable laser system. The system automatically makes and places solder preforms on one panel while simultaneously laser soldering pins on a second panel. The laser soldering system is effective for high-volume selective soldering of wire-wrapping pins to backplanes, power planes, and PCBs.

laser trim—The adjustment (upward in resistance) of a film resistor value by applying heat from a focused laser source to remove material, i.e., to cut a kerf.

laser trimming—An IC trimming technique that involves focusing a laser on the die to disconnect resistors.

laser welder—A system, similar to a laser drill, that uses the heat from a pulsed laser to weld metals. Because of the rapidity and localization with which the welding takes place, metals of vastly dissimilar melting points can be welded with this system.

laser welding—Process in which thermal energy released by a laser impinging on the surface of a metal is conducted into the bulk of the metal workpiece by thermal conduction, bonding component leads to highly conductive materials, such as copper printed circuitry.

lasing—1. The phenomenon that occurs when resonant frequency controlled energy is coupled to a specially prepared material, such as a uniformly doped semiconductor crystal that has free-moving or highly mobile, loosely coupled electrons. As a result of resonance and the imparting of energy by collision or close approach, electrons are raised to highly excited energy states; when they move to lower states, they cause quanta of high-energy electromagnetic radiation to be released as coherent light waves. This action takes place in a laser. 2. A unique mode of light production by stimulated emission from excited atoms. The uniqueness of the lasing process is that the light thereby generated tends to be a single frequency, coherent in time and space.

lasing condition or state—The condition of an injection laser corresponding to the emission of predominantly coherent or stimulated radiation.

latch—1. A feedback loop used in a symmetrical digital circuit (such as a flip-flop) to retain a state. 2. A simple logic storage element. The most basic form consists of two cross-coupled logic gates that store a pulse applied to one logic input until a pulse is applied to the other input; thus, the complementary information is stored in the latch. 3. A name commonly used to refer to a flip-flop (usually a D type) when used for data storage, as opposed to counting and logic functions. 4. To lock into a certain location or state.

latching—A technique for storing an event such as the momentary breaking of a perimeter circuit. The fact that the event has occurred will be available until the latched circuit has been reset. *See* alarm hold.

latching current—The minimum value of principal current required to maintain a thyristor in the on state after switching from the off state to the on state has occurred and the trigger signal has been removed.

latching relay—Also called bistable relay. 1. A relay with contacts that lock in either the energized or deenergized position, or both, until reset either manually or electrically. 2. A relay with two separate coils, one of which must be energized to change the state of the relay, which will remain in either state without the need for external power. 3. A relay that includes a means of holding the state of the relay in the last or latched position. In effect, the relay has a memory, because the contacts remain open or closed when the coil is not actuated. To change state, the latching relay coil must be reenergized.

latching sensor—A solid-state Hall-effect sensor that has a plus (south pole) maximum and minimum operate point, and a minus (north pole) maximum and minimum release point. Thus, when the sensor is operated with a south pole, it will stay in the operated condition even with removal of the south pole magnet and will release only in the presence of a north pole.

latch-in relay—Also called locking relay. A relay with contacts that remain energized or deenergized until reset manually or electrically.

Latch-in relay.

latch mode—A mode of operation for a storage circuit in which all encoder contact closures, even momentary ones, are latched “on.”

latch-up—1. A condition in which the collector voltage in a given circuit does not return to the supply voltage when a transistor is switched from saturation to cutoff. Instead, the collector finds a stable operating point in the avalanche region of the collector characteristics. 2. An unintended stable circuit mode that will not revert to a previous intended circuit mode after removal of a stimulus such as a spurious signal or radiation. The effect is usually caused by parasitic circuit elements. 3. The characteristic of some op amps to remain in positive or negative saturation after their maximum differential input voltage is exceeded. 4. The switching of an electronic circuit to an unintended mode by improper voltage application. 5. An undesirable phenomenon in which either a pnpn or an npnp thyristor-type parasitic structure suddenly turns to an on state, thereby bypassing or shorting out portions of an IC.

latch voltage—The effective input voltage at which a flip-flop changes states.

late contacts—In a relay, contacts that open or close after other contacts when the relay operates.

latency—1. In a serial storage computer system, the time necessary for the desired storage location to appear under the drum heads. 2. In computers, the time required to establish communication with a specific storage location, not including transfer time, i.e., access time less word time. 3. A state of seeming inactivity, such as that occurring between the instant of stimulation and the beginning of response. 4. A delay encountered in a computer when waiting for a specific response. Latency is caused by propagation delays and the queuing of disks or tapes when randomly addressed.

latency time—The time required to shift to any given bit (word) in a serial memory, such as in CCDs and bubble memories.

latent image—A stored image (e.g., the one contained in the charged mosaic capacitance in an iconoscope).

lateral chromatic aberration—Aberration that affects the sharpness of images off the axis. This occurs because different colors produce different magnifications.

lateral compliance—The force required to move the reproducing stylus from side to side as it follows the modulation on a laterally recorded record.

lateral-correction magnet—In a three-gun picture tube, an auxiliary component used for positioning the blue beam horizontally so that beam convergence will

be obtained. It operates on the principle of magnetic convergence and is used in conjunction with a set of pole pieces mounted on the focus element of the blue gun.

lateral forced-air cooling—A method of heat transfer that employs a blower to produce side to side circulation of air through or across the heat dissipators.

lateral loss—A power loss, expressed in decibels, due to the deviation from optimum coaxial alignment of the ends of separable optical conductors.

lateral recording—A mechanical recording in which the groove modulation is perpendicular to the direction of motion of the recording medium and parallel to its surface.

latex—Rubber material used for insulation of wire.

lattice—1. In navigation, a pattern of identifiable intersection lines placed in fixed positions with respect to the transmitters that establish them. 2. The geometrical arrangement of atoms in a crystalline material.

lattice network—A network composed of four branches connected in series to form a mesh. Two nonadjacent junction points serve as input terminals, and the remaining two as output terminals.

lattice structure—In a crystal, a stable arrangement of atoms and their electron-pair bonds.

lattice-wound coil—*See* honeycomb coil.

launch angle—In an optical fiber or fiber bundle, the angle between the input radiation vector, i.e., the input light chief ray, and the axis of the fiber radiation vector, i.e., the axis of the fiber or fiber bundle. If the ends of the fibers are perpendicular to the axis of the fibers, the launch angle is equal to the angle of incidence when the ray is external and the angle of refraction when initially inside the fiber.

launch complex—The entire launch, control, and support system required for launching rockets.

launching—The transferring of energy from a coaxial cable or shielded paired cable in a waveguide.

lavalier microphone—A microphone with acoustical and vibration-isolation properties suiting it to use for speech pickup from a position on the speaker’s chest. Lavalier mikes are fitted with a band or strap for hanging around the neck, and are frequently used when it is important that the mike not be conspicuously visible (as to a TV audience). The use of this mike frees the speaker’s hands and allows a certain amount of freedom to move about.

lawn mower—1. In facsimile, a term often used when referring to a helix-type recorder mechanism. 2. A type of rf preamplifier used with a radar receiver.

law of electric charges—Like charges repel; unlike charges attract. *See also* Coulomb’s law.

law of electromagnetic induction—*See* Faraday’s laws, 3.

law of electromagnetic systems—Every electromagnetic system tends to change its configuration so that the flux of magnetic induction will be a maximum.

law of electrostatic attraction—*See* Coulomb’s law.

law of magnetism—Like poles repel; unlike poles attract.

law of normal distribution—The Gaussian law of the frequency distribution of any normal, repetitive function. It describes the probability of the occurrence of deviants from the average.

law of reflection—The angle of reflection is equal to the angle of incidence—i.e., the incident, reflected, and normal rays all lie in the same plane.

laws of electric networks—*See* Kirchhoff’s laws, 1 and 2.

lay—1. Pertaining to wire and cable, the axial distance required for one cable conductor or conductor strand

to complete one revolution about the axis around which it is cabled. 2. The distance between successive points where the same strand (or insulated conductor) when twisted with one or more strands (or insulated conductors) presents itself in the same position. 3. The length measured along the axis of a wire or cable required for a single strand (in stranded wire) or conductor (in cable) to make one complete turn about the axis of the conductor or cable.

layer—1. The consecutive turns of a coil lying in a single plane. 2. One of several films in a multiple-film structure on a substrate.

layer-to-layer adhesion—The tendency for adjacent layers of recording tape in a roll to adhere, particularly after prolonged storage under conditions of high temperature and/or humidity.

layer-to-layer signal transfer—The magnetization of a layer of tape in a roll by the field from a nearby recorded layer. The magnitude of the induced signal tends to increase with storage time and temperature, and to decrease after the tape is unwound. These changes are a function of the magnetic instability of the oxide.

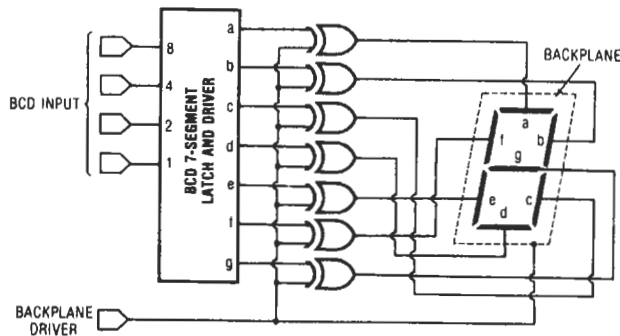

layer-to-layer spacing—The thickness of dielectric material between adjacent layers of conductive circuitry in a multilayer printed board.

layer winding—A coil-winding method in which adjacent turns are placed side by side and touch each other. Additional layers may be wound over the first and are usually separated by sheets of insulation.

layout—1. Diagram indicating the positions of parts on a chassis or panel. 2. The actual positions of the parts themselves. 3. The topological arrangement of conductors

Construction.

Drive electronics.

and components in the design of integrated circuits. It precedes the artwork. 4. A visual representation of a complete physical entity, usually to scale.

layout wiring drawing—A type of circuit diagram, made to show explicitly each wire, its gage, color coding, and terminations.

lay-up—The technique of registering and stacking layers of a multilayer board before the laminating cycle.

L-band—1. Microwave band in which the wavelengths are at or near 23.5 cm. 2. A radio-frequency band of 390 to 1550 MHz and corresponding wavelengths of 77 to 19 cm. Used for mobile communications.

L-carrier system—A telephone carrier system employed on coaxial-cable systems and microwave line-of-sight and tropospheric-scatter radio systems. It occupies a frequency band extending from 68 kHz to over 8 MHz.

LCC—Abbreviation for leadless chip carrier. A surface-mounted package having metallized contacts (terminals) at its periphery. Usually made of ceramic material.

LCD—Abbreviation for liquid crystal display. 1. A seven-segment (typically) display device consisting basically of a liquid crystal hermetically sealed between two glass plates. One type of LCD (dynamic scattering) depends on ambient light for its operation, while a second type depends on a backlighting source. The readout is either dark characters on a dull white background or white on a dull black background. LCDs have very low power requirements. 2. A display whose segments or elements consist of transparent electrodes etched on glass separated by a liquid that has some crystalline properties, including orderly molecular alignment. Voltage applied to opposing electrodes alters the alignment in the liquid between them, affecting the passage of light through the region (reflected or transmitted), rendering the segments visible by contrast. 3. An optically passive device, in that it does not generate light to produce contrast, whose operation depends on the ability of the liquid crystal to rotate plane-polarized light relative to a pair of crossed polarizers attached to the outside of the display. Rotation of the plane of polarization is a function of the applied field and decreases with increasing field or voltage.

LC product—Inductance (L) in henrys multiplied by capacitance (C) in farads. See figure on p. 416.

L/C ratio—Inductance in henrys divided by capacitance in farads.

LCS—Abbreviation for loudness-contour selector.

L cut—A trim notch in a film resistor that is created by the cut starting perpendicular to the resistor length and turning 90° to complete the trim parallel to the resistor axis, thereby creating an L-shaped cut.

LD—See laser diode.

LD coupler—See laser diode coupler.

LDCS—Abbreviation for long-distance control system. A computer-based communication management system (Datapoint Corporation) that routes long-distance calls over least-cost lines and maintains accounting data on calls.

L-display—Also called L-scan. A radar display in which the target indication appears as two horizontal blips, one extending to the right and one to the left from a vertical time base. Azimuth pointing error is indicated by relative blip amplitude, and range is indicated by the position of the signal along the base line.

leaching—The process of dissolving and removing impurities and soluble components from plated items, tank materials, and the like.

lead—1. A wire to or from a circuit element. 2. To precede (the opposite of lag). 3. A wire, with or without

terminals, that connects two points in a circuit. 4. A conductive path that is usually self-supporting.

lead-acid cell—Also called lead cell. A cell in an ordinary storage battery. It consists of electrodes (plates) immersed in an electrolyte of dilute sulfuric acid. The electrodes contain certain lead oxides that change their composition as the cell is charged or discharged.

Lead-acid cell.

lead-acid storage cell—A storage cell in which both plates are lead-antimony or lead-calcium grids filled with spongy lead for the negative plate and lead peroxide for the positive plate. During discharge, the material in both plates is converted to lead sulfide. The electrolyte is a solution of sulfuric acid with a specific gravity of 1.200. The cell voltage is nominally 2 volts but rises to 2.15 volts on float and drops to 1.85 volts on discharge.

lead cell—See lead-acid cell.

lead-covered cable—A cable with a lead sheath. The sheath offers protection from the weather and mechanical damage to the wires contained therein.

lead dress—The placement or routing of wire and component leads in an electrical circuit.

leader—1. Special nonmagnetic tape that can be spliced to either end of a magnetic tape to prevent damage and possible loss of recorded material and to indicate visually where the recorded portion of the tape begins and ends. 2. Tough, nonmagnetic tape spliced ahead of the recorded material on a tape that is expected to receive rough or frequent handling. Usually has one matte-finished surface for writing on, and often available in a variety of colors for coding purposes.

leader cable—A navigational aid in which the path to be followed is defined by a magnetic field around a cable.

leader tape—Also called timing tape. Plain nonmagnetic tape for splicing to either end of magnetic tape to facilitate threading and preserve recorded material, or for splicing between recorded tapes to separate selections or provide pauses.

lead frame—1. A metal frame that holds the leads of a plastic encapsulated package (DIP) in place before encapsulation and is cut away after encapsulation. 2. The metal part of a solid-state device package that achieves electrical connection between the die and other parts of the system of which the IC is a component. Large-scale integrated circuits are welded onto lead frames in such a way that leads are available to facilitate making connections to and from the various solid-state devices

to the packages. 3. The metallic portion of the device package that completes the electrical connection path from the die or dice and from ancillary hybrid circuit elements to external circuits.

lead-in—The conductor that provides the path for rf energy between the antenna and the radio/television receiver or transmitter.

leading blacks—Also called edge effect. In a television picture, the condition in which the edge preceding a white object is overshadowed toward black (i.e., the object appears to have a preceding, or leading, black border).

leading current—1. Current that reaches maximum before the voltage that produces it does. A leading current flows in any predominantly capacitive circuit. 2. In an alternating-current circuit in which the net reactance is capacitive, a current wave that precedes in phase the voltage wave that produces it.

Leading current.

leading edge—That transition of a pulse which occurs first.

leading-edge pulse time—The time required by a pulse to rise from its instantaneous amplitude to a stated fraction of its peak amplitude.

leading ghost—A twin image appearing to the left of the original in a televised picture.

leading load—A predominantly capacitive load—i.e., one in which the current leads the voltage.

lead-in groove—Also called a lead-in spiral. A blank spiral groove around the outside of the record. Its pitch is usually much greater than the other grooves and is used to quickly lead the needle into the beginning of the recorded groove.

leading whites—Also called edge effect. In a television picture, the condition in which the edge preceding a black object is shaded toward white (i.e., the object appears to have a preceding, or leading, white border).

leading zeros—Zeros placed in front of a number to use up all blanks spaces in a data field.

lead-in insulator—A tubular insulator through which cables or wires are brought inside a building.

lead-in spiral—See lead-in groove.

lead-in wires—Wires that carry current into a building (e.g., from an antenna). See down lead.

lead-length compensation—In dc ammeters for use with external shunts, the leads that connect to the shunt become an integral part of the total instrument. An adjustable resistor is often included to compensate for the resistance of the leads and to improve overall accuracy.

leadless chip carrier—See LCC.

leadless inverted device—Abbreviated LID. A shaped metallized ceramic form used as an intermediate carrier for semiconductor chip devices, especially adapted for attachment to conductor lands of a thick- or thin-film network by reflow solder bonding.

Leadless inverted devices.

lead network—A network, either ac or dc, designed to provide error-rate damping in the controlling device of a servo system.

lead-out groove—Also called a throw-out spiral. A blank spiral groove on the inside of a recording disc, next to the label. It is generally much deeper than the recording groove and is connected to either the locked or eccentric groove.

lead-over groove—Also called a crossover spiral. On disc records containing several selections, the groove in which the needle travels as it crosses from one selection to the next.

lead polarity of transformer—Also called polarity. A designation of the relative instantaneous directions of currents in the leads of the transformer. Primary and secondary leads are said to have the same polarity when, at a given instant, the current enters the primary lead in question and leaves the secondary lead in question in the same direction as though the two leads formed a continuous circuit.

lead screw—1. In a recording, a threaded road that guides the cutter or reproducer across the surface of a disc. 2. In facsimile, a threaded shaft that moves the scanning mechanism or drum lengthwise.

lead selenide (PbSe) cell—A thin-film photoconductive cell that is sensitive to the infrared region. The photosensitive material of the cell is composed of lead selenide, and the cell is used in the detection of infrared radiation.

lead sulfide (PbS) cell—A photoconductive cell having its greatest sensitivity in the infrared region. The photosensitive material of the cell is lead sulfide, which is deposited on a glass plate.

lead time—In the display of a random sampling oscilloscope, the interval represented that occurs immediately before trigger recognition.

lead wires—Wire conductors for intraconnections or input/output leads.

leaf insulator—Leaf-spring-shaped insulator located in a switch stack adjacent to a contact spring or actuator spring to keep that spring from making electrical contact with an adjacent spring or other metallic surface.

leak—A condition that causes current to be shunted away from its destination through a low resistance.

leakage—1. Undesired flow of electricity over or through an insulator. 2. The portion not utilized most effectively in a magnetic field (e.g., at the end pieces of an electromagnet).

leakage coefficient—Ratio of total to useful flux produced in the neutral section of a magnet.

leakage current—1. An undesirable small-value stray current that flows through (or across the surface of) an insulator or the dielectric of a capacitor. 2. A current that flows between two or more electrodes in a tube other than across the interelectrode space. 3. Current prior to switching at a specified voltage. 4. Undesirable flow of current through or over a surface of an insulating material or insulator. 5. All currents, including capacitively coupled currents, that may be conveyed between energized parts of a circuit and ground or other parts. 6. The conduction current through a capacitor when a direct voltage is applied.

leakage flux—The flux that does not pass through the air gap, or useful part, of the magnetic circuit.

leakage inductance—A self-inductance due to the leakage flux generated in the winding of a transformer.

leakage power—In tr and pre-tr tubes, the radio-frequency power transmitted through a fired tube.

leakage radiation—Spurious radiation in a transmitting system — i.e., radiation from other than the system itself.

leakage rate—A laboratory procedure used to determine the amount and duration of resistance of an article to a specific set of destructive forces or conditions.

leakage reactance—1. The reactance represented by the difference in value between two mutually coupled inductances when their fields are aiding and then opposing. 2. That portion of the reactance of a transformer primary which is due only to leakage flux.

leakage resistance—The normally high resistance of the path over which leakage current flows.

leakance—The reciprocal of insulation resistance.

leaktight—See hermetic.

leaky—Usually applied to a capacitor in which the resistance has dropped so far below normal that objectionably high leakage current flows.

leaky waveguide—A waveguide with a narrow longitudinal slot, permitting a continuous energy leak.

leaky waveguide antenna—An antenna constructed from a long waveguide with radiating elements along its length. It has a very sharp pattern.

leapfrogging—The process of phasing, or delaying, the ranging pulse of a tracking radar in order to move or shift (on the scope presentation) the tracking gate (at target blip) past the target blip from another radar.

leapfrog test—A computer check routine using a program that calls for performing a series of arithmetical or logical operations on one section of memory locations, transferring to another section, checking correctness of transfer, and repeating the series of operations. Eventually, all storage positions are checked by this process.

learning curve—The improvement that occurs in manufacturing processes with experience.

leased line—Also called dedicated or private line. A semipermanent leased telephone circuit that connects two or more points and is continuously available to the subscriber. See also dedicated line.

least maximum deviation—A manner of expressing nonlinearity as a deviation from a straight line for which the deviations for proportional or normal linearity are minimized.

least mechanical equivalent of light—The radiant power that is contained in 1 lumen at the wavelength of maximum visibility. It is equal to 1.46 milliwatts at a wavelength of 555 nanometers.

least significant bit—Abbreviated LSB. 1. In a system in which a numerical magnitude is represented by a series of binary (i.e., two-valued) digits, that digit (or bit) that carries the smallest value or weight; usually the rightmost bit. 2. The lowest-order bit or the bit with the least weight. Binary digit having a weight of 2^0 , or 1. 3. Smallest value that can be digitized; lowest-order digital output.

least significant digit—Abbreviated LSD. 1. The digit that has the lowest place value in a number; usually the rightmost digit. 2. Number at the extreme right of a group of numbers. Example: 6937. Digit 7 is the LSD.

least voltage coincidence detection—Abbreviated LVCD. A system that provides protection against interfering signals by blocking all signals except those having a pulse-repetition frequency the same as or some exact multiple of the radar-set pulse-repetition frequency.

Lecher line—See Lecher wire.

Lecher oscillator—A device for producing standing waves on two parallel wires called Lecher wires.

Lecher oscillator.

Lecher wire—1. A type of transmission line used to measure wavelength, consisting of a pair of wires whose electrical length is adjustable. If a source of radio frequency is coupled to one end of the line and the line is adjusted until a set of standing waves is formed, the wavelength may be determined by measurement of the distance between adjacent nodes. 2. Two parallel wires with a movable shunt that are connected to the output of a radio-frequency source and are used mainly to measure wavelengths shorter than about 10 meters.

Leclanche cell—1. Type of dry cell comprising a positive carbon pole contained in a porous vessel filled with manganese dioxide, the whole assembly standing in a container of an ammonium chloride solution that also contains the negative zinc pole. The electromotive force generated by a cell of this type is approximately 1.5 volts. 2. An ordinary dry cell. It is a primary cell with a positive electrode of carbon and a negative electrode of zinc in an electrolyte of sal ammoniac and a depolarizer of manganese dioxide.

LED—Abbreviation for light-emitting diode. 1. A pn junction semiconductor device specifically designed to

emit light when forward biased. This light can be one of several visible colors—red, amber yellow, or green—or it may be infrared and thus invisible. Electrically, a LED is similar to a conventional diode in that it has a relatively low forward voltage threshold. Once this threshold is exceeded, the junction has a low impedance and conducts current readily. This current must be limited by an external circuit, usually a resistor. The amount of light emitted by a LED is proportional to the forward current over a broad range, thus it is easily controlled, either linearly or by pulsing. The LED is extremely fast in its light output response after the application of forward current. Typically, the rise and fall times are measured in nanoseconds. LEDs are constructed in either a multisegment (typically seven segments) display format or a dot-matrix display format. Red is used most often because of its lower cost. 2. A diode that operates similar to a laser diode, with the same output power level, the same output limiting modulation rate, and the same operational current densities, i.e., thousands of amperes per square centimeter, which causes catastrophic and graceful degradation, but with greater simplicity, tolerance, and ruggedness and about ten times the spectral width of its radiation.

Layering.

Construction.

Symbol.

LED.

ledger balance—A facility used with message switching equipment to ensure that no messages are lost within the center. It involves comparing the number of addresses received with the number of addresses transmitted.

left-handed polarized wave—Also called counterclockwise-polarized wave. An elliptically polarized transverse electromagnetic wave in which the electric intensity

vector rotates counterclockwise (looking in the direction of propagation).

left-hand rule—See Fleming's rule, 1.

left-hand taper—The greater resistance in the counterclockwise half of the operating range of a rheostat or potentiometer than in the clockwise half (looking from the shaft end).

left (or right) signal—The electrical output of a microphone or combination of microphones placed so as to convey the intensity, time, and location of sound originating predominantly to the listener's left (or right) of the center of the performing area.

left (or right) stereophonic channel—The left (or right) signal as electrically reproduced in the reception of FM stereophonic broadcasts.

leg—A section or branch of a component or system (e.g., one of the windings of a transformer).

legend—A table of symbols or other data placed on a map, chart, or diagram to assist the reader in interpreting it.

Lenard rays—Cathode rays that emerge from a special vacuum tube through a thin glass window or metallic foil.

Lenard tube—An electron tube in which the beam can be taken through a section of the wall of the evacuated enclosure.

length of a scanning line—1. The length of the path traced by the scanning or recording spot as it moves from line to line. 2. On drum-type equipment, the circumference of the drum. 3. The spot speed divided by the scanning-line frequency.

lens—1. An optical device that focuses light by refraction. 2. An electrical device that focuses microwaves by refraction or diffraction. 3. An acoustic device that concentrates sound waves by refraction. 4. An electronic optical device that focuses electrons. 5. A transparent optical component consisting of one or more pieces of optical glass with surfaces so curved (usually spherical) that they serve to converge or diverge the transmitted rays of an object, thus forming a real or virtual image of that object.

lens antenna—A microwave antenna with a dielectric lens placed in front of the dipole or horn radiator so that the radiated energy is concentrated into a narrow beam.

lens disc—A television scanning disc having a number of openings arranged in a spiral, with a lens set into each opening.

lens speed—Refers to the ability of a lens to transmit light, represented as the ratio of the focal length to the diameter of the lens. A fast lens would be rated $f/1.2$; a much slower lens might be designated as $f/8$. The larger the f -number, the slower the lens.

lens turret—On a camera, an arrangement that accommodates several lenses and can be rotated to facilitate their rapid interchange.

Lenz's law—The current induced in a circuit due to a change in the magnetic flux through it or to its motion in a magnetic field is so directed as to oppose the change in flux or to exert a mechanical force opposing the motion. If a constant current flows in a primary circuit A and if, by motion of A or the secondary circuit B, a current is induced in B, the direction of the induced current will be such that, by its electromagnetic action on A, it tends to oppose the relative motion of the circuits.

LEO—Abbreviation for low earth orbit. Any orbit around the earth substantially below the geostationary satellite orbit, generally within several hundred kilometers above the earth's surface and usually inclined to the equatorial plane.

Lepel discharger—A quenched spark gap used in early radiotelegraph transmitters employing shock excitation.

letter quality—Resembling the output of a typewriter.

letter-quality printer—A machine that prints like a typewriter, by pressing complete characters through a ribbon onto paper.

letters shift—In the Baudot code, a control character following which all characters are interpreted as being in the group containing letters (lower case).

let-through current—The current that actually passes through a circuit breaker under short-circuit conditions.

level—1. The magnitude of a quantity in relation to an arbitrary reference value. Level normally is stated in the same units as the quantity being measured (e.g., volts, ohms, etc.). However, it may be stated in units that express the ratio to a reference value (e.g., decibels). 2. A voltage that remains constant over a long period of time. 3. In describing codes or characters, a bit or element. 4. The intensity of an electrical signal.

level above threshold—Also called sensation level. The pressure level of a sound in decibels above its threshold of audibility for the individual listener.

level compensator—1. An automatic gain control that minimizes the effect of amplitude variations in the received signal. 2. A device that automatically controls the gain in telegraph-receiving equipment.

level indicator—A device for showing visually the level of the audio signal, as a means of establishing the optimum amount of signal being fed to the tape.

level shifting—The process of changing a differential signal input to a single-ended output within an operational amplifier.

level translator—A circuit that accepts digital input signals at one pair of voltage levels and delivers output signals at a different pair of voltage levels. For example, a circuit to translate the -0.8-V “zero” and 1.6-V “one” of ECL to the -0.8-V “zero” and -4.2-V “one” suitable for COS/MOS.

level-triggered flip-flop—A flip-flop that responds to the voltage level rather than the rate of change of an input signal.

lever switch—Commonly referred to as a key lever or lever key. 1. A hand-operated switch for rapidly opening and closing a circuit. 2. A switch having a lever (toggle), whose movement results either directly or indirectly in the connection or disconnection of the switch terminations in a specified manner.

Lewis antenna—A microwave scanning antenna consisting of a lensed flat horn that tapers to a narrow rectangular opening across which a waveguide feed can be moved to scan the beam. The horn is folded by the incorporation of a 45° reflecting strip, and the thin rectangular end is formed into a circular annulus, around which the feed can be rotated. The deformed parallel-plate region that results has a conical shape with the feed circle as base.

Leyden jar—The original capacitor. It consists of metal foil sheets on the inside and outside of a glass jar. The foil serves as the plates and the glass as the dielectric.

LF—Abbreviation for low frequency (i.e., between 30 and 300 kHz).

LFM—A VHF fan-type marker. It is low powered (5 watts) and has a range of only 10 miles or less.

librarian—A system program that is responsible for creating, editing, and deleting software libraries.

library—1. A collection, usually stored on magnetic tape, of computer programs or subroutines for special purposes. 2. A group of standard, proven computer routines

Lepel discharger — lifetime

Leyden jar.

that can be incorporated into larger routines. 3. A collection of system and/or user tasks that may be executed by other tasks in the system. The major reason for libraries is to prevent software redesign each time a function is needed by a task. 4. A set of frequently used programs or program pieces.

LIC—Abbreviation for linear integrated circuit.

Lichtenberg figure camera—Also called klydonograph or surge-voltage recorder. A device for indicating the polarity and approximate crest value of a voltage surge by the appearance and dimensions of the Lichtenberg figure produced on a photographic plate or film. The emulsion coating of the plate or film contacts a small electrode coupled to the circuit in which the surge occurs. The film is backed by an extended plane electrode.

LID—See leadless inverted device.

lie detector—Also called a polygraph. An electronic instrument that measures the blood pressure, temperature, heart action, breathing, and skin moisture of the human body. Abrupt or violent changes in these variables are said to indicate that the subject is not telling the truth.

LIF connector—Abbreviation for low insertion force connector. Type of printed circuit board connector unit in which mating and unmating forces are reduced 70 to 90 percent. Typical engaging and separating forces in these devices are 0.5 oz/contact, contrasted with the 8 to 16 oz required for conventional printed circuit board connectors.

life—1. The expected number of full excursions over which a transducer would operate within the limits of the applicable specification. 2. The number of performance hours, days, years, or actual operations an item is designated to meet.

life aging—1. Burn-in test that moderates the elevation of temperature and extends the time period in order to test the overall device quality as opposed to infant mortality. 2. Long-period operation of items, components, or devices to test the consistency of device finality.

life cycle—A test that indicates the time span before failure; the test occurs in a controlled, usually accelerated environment.

life test—The test of a component or unit under the conditions that approximate, or simulate by acceleration, a normal lifetime of use. The test is performed to determine life expectancy or reliability throughout a predetermined life expectancy.

lifetime—1. The average time interval between the introduction and recombination of minority carriers in a semiconductor. 2. The time it takes a thermally generated or photogenerated electron-hole pair to recombine.

LIFO—Last in, first out; method of storing and retrieving data in a stack, table, or list. *Compare* FIFO.

lifter—In a tape recorder, a movable rod or guide that draws the tape away from the heads during fast-forward or rewind modes to eliminate needless head wear. Lifters work automatically on most machines in either high-speed mode.

lifting magnet—A powerful electromagnet used on the end of a crane to lift iron and steel objects, which can be dropped instantly by merely cutting off the current.

light—1. Radiant energy within the wavelength limits perceptible by the average human eye (roughly, between 400 and 700 nanometers). Although ultraviolet and infrared emissions will excite some types of photocells, they are usually not considered light. 2. In combination with other terms, a device used as a source of luminous energy (e.g., a pilot light). 3. Radiant energy transmitted by wave motion with wavelengths from about 0.3 μm to 30 μm ; this includes visible wavelengths (0.38 μm to 0.78 μm and those wavelengths such as ultraviolet and infrared, which can be handled by optical techniques used for the visible region. In more restricted usage, radiant energy within the limits of the visual spectrum.

Light, 1 (spectrum).

light-activated silicon-controlled switch—*See* LASCS.

light-activated switch—A semiconductor diode that is triggered into conduction by light irradiation of a light-sensitive part of the semiconductor pellet.

light amplifier—A device that serves to emit light of the same wavelength as the input light, only with an increase in intensity. It may be a solid-state device comprised of photoconductive and luminescent layers contained between two electrodes.

light-beam cathode-ray-tube recorder—Recorder using an electron beam to make multiple traces on a CRT screen. Traces are reflected from a fixed plane mirror onto moving photosensitive paper via an optical system.

light-beam galvanometer—A modified form of the D'Arsonval meter movement in which a small mirror is cemented to a moving coil mounted in the field of a permanent magnet. Current through the coil causes the coil to be deflected angularly, and the mirror reflects a beam of light onto a moving strip of photographic paper. The developed chart shows the waveform of the current through the coil.

light-beam instrument—An instrument in which a beam of light is the indicator.

light-beam oscillograph—Recorder using a mirror on a galvanometer to achieve recording response to 5 kHz.

Light-beam oscillograph.

light-beam pickup—A phonograph pickup utilizing a beam of light as a coupling element of the transducer.

light chopper—A device for interrupting a light beam. It is frequently used to facilitate amplification of the output of a phototube on which the beam strikes.

light current—The current that flows through a photosensitive device, such as a phototransistor or a photodiode, when it is exposed to illumination or irradiance.

light-dimming control—A circuit, often employing a saturable reactor, used to control the brightness of the lights in theaters, auditoriums, etc.

light-emitting diode—Abbreviated LED. A pn junction that emits light when biased in the forward direction. *See* LED.

light-emitting diode coupler—Abbreviated LED coupler. A coupling device that enables the coupling of light energy from a light-emitting diode (LED) source to an optical fiber or cable at the transmitting end of an optical fiber data link. The coupler may be an optical fiber pigtail epoxied to the LED.

light-activated silicon-controlled rectifier—*See* LASCR.

light flux—See luminous flux, 1.

light guide—1. An assembly of optical fibers and other optical elements mounted and finished in a component that is used to transmit light. 2. A conduit made up of fibers randomly collected or bunched in a group; it conducts light and images.

light gun—A photoelectric cell used by computer operators to take specific actions in assisting and directing computer operation. So called because of its gun-like case.

lighthouse tube—An ultrahigh-frequency electron tube shaped like a lighthouse and having disc-sealed planar elements. See also disc-seal tube.

Lighthouse tube (cutaway view).

lighting outlet—An outlet for direct connection of a lamp holder, lighting fixture, or pendant cord termination in a lamp holder.

light intensity cutoff—In a photoelectric alarm system, the percent reduction of light that initiates an alarm signal at the photoelectric receiver unit.

light level—The amount of (or intensity of) light falling upon a subject.

light load—A fraction of the total load the device is designed to handle.

light meter—An electron device that contains a photosensitive cell and calibrated meter for the measurement of light levels.

light microsecond—The unit for expressing electrical distance. It is the distance over which light travels in free space in 1 microsecond (i.e., about 983 feet, or 300 meters).

light modulation—Variation in the intensity of light, usually at audio frequencies, for communications or motion-picture sound purposes.

light modulator—The device for producing the sound track on a motion-picture film. It consists of a source of light, an appropriate optical system, and a means for varying the resulting light beam (such as a galvanometer or light valve).

light negative—Having a negative photoconductivity when subjected to light.

lightning arrester—A device to prevent damage to electrical equipment by transient overvoltages whether from lightning or switching. Spark gaps that can only be bridged by voltages above those used in the equipment allow the higher voltages to be discharged to ground.

lightning generator—A generator of high-voltage surge (e.g., for testing insulators).

lightning rod—A pointed metal rod carried above the highest point of a pole or building, and connected to earth by a heavy copper conductor, for the purpose of carrying a direct lightning discharge directly to earth without damage to the protected structure.

lightning surge—A transient disturbance in an electric circuit caused by lightning.

lightning switch—A switch for connecting a radio antenna to ground during electrical storms.

light pen—1. A light-sensitive device used with a computer-operated CRT display for selecting a portion of the display for action by the computer. 2. A photosensor placed in the end of a penlike probe. It is used in conjunction with a CRT display for drawing, erasing, or location characters. Operation is by comparison of the time it senses a light pulse to the scanning time of the display. 3. A hand-held data-entry device used only with refresh displays. It consists of an optical lens and photocell, with associated circuitry, mounted in a wand. Most light pens have a switch on the barrel that makes the pen sensitive to light from the screen. An activated light pen, when pointed at a vector or character on the screen, will generate an interrupt. It is then possible to identify the vector or character since the display stopped refreshing when the item was drawn that caused the interrupt. The most common uses of light pens are light-button selection and tracking.

light pencil—A narrow cone of light rays that diverges from a point source or converges to an image point.

light pipe—1. A bundle of transparent fibers that can transmit light around corners with small losses. Each fiber transmits a portion of the images through its length, reflection being caused by the lower refractive index of the surrounding material, usually air. 2. Transparent matter that usually is drawn into a cylindrical or conical shape through which light is channeled from one end to the other by total internal reflections. Optical fibers are examples of light pipes.

light positive—Having positive photoconductivity—i.e., increasing in conductivity when subjected to light.

light-powered telephone—Technology that relies on a highly efficient photodetector that can detect incoming light signals at one frequency and transmit outgoing signals at another, thus permitting the sending and receiving of light signals over one fiber with a single device.

light ray—1. A very thin beam of light. 2. A line, perpendicular to the wavefront of light waves, indicating their direction of travel and representing the light wave itself.

light relay—A photoelectric device that opens or closes a relay when the intensity of a light beam changes.

light-sail—A method of spacecraft propulsion using a giant sail to catch the solar wind, a nonfictional stream of ionized gas particles constantly emitted from the sun at speeds of up to 2 million miles an hour (3.2 million kilometers per hour).

light sensitive—Exhibiting a photoelectric effect when irradiated (e.g., photoelectric emission, photoconductivity, and photovoltaic action).

light-sensitive Darlington amplifier—Two stages of transistor amplification in one light-detector device. Darlington's give much higher gain than single transistors.

light-sensitive tube—A vacuum tube that changes its electrical characteristics with the amount of illumination.

light source—Any object capable of emitting light. (In fiber optics, the light source is normally either an LED or a laser.)

light source power—The electrical power used to stimulate any light source. Power supplies may be step-up or stepdown transformers; rectifiers to convert ac to dc; ammeters and voltmeters to observe the input to the source; and regulators and variable resistors, for maintaining constancy of input.

light-spot scanner—Also called a flying-spot scanner. A television camera in which the source of illumination is a spot of light that scans the scene to be televised. The picture signal is generated in a phototube, which picks up light either transmitted through the scene or reflected from it.

Light-spot scanner.

voice equipment designed with proper recognition processing algorithms.

limited signal—In radar, a signal that is intentionally limited in amplitude by the dynamic range of the system.

limited space-charge accumulation—A mode of oscillation for gallium arsenide diodes.

limited space-charge accumulation diode—See LSA diode.

limited stability—The property of a system that remains stable only as long as the input signal falls within a particular range.

limiter—1. A device in which some characteristic of the output is automatically prevented from exceeding a predetermined value—e.g., a transducer in which the output amplitude is substantially linear (with regard to the input) up to a predetermined value and substantially constant thereafter. 2. A radio-receiver stage or circuit that limits the amplitude of the signals and hence keeps interfering noise low by removing excessive amplitude variations from the signals. 3. A device that reduces the intensity of very short duration peaks (transient peaks) in the audio signal without audibly affecting dynamic range. 4. A feedback element that acts to restrain a variable by modifying or replacing the function of the primary element when predetermined conditions have been reached.

Limiter action.

light valve—A device whose light transmission can be varied in accordance with an externally applied electrical quantity such as voltage, current, an electric or magnetic field, or an electron beam.

lightwave communications—Also called optical communications. 1. In fiber optics communications, using light, instead of an electric current, to carry the information. 2. That aspect of communications and telecommunications devoted to the development and use of equipment that uses electromagnetic waves in or near the visible region of the spectrum for communication purposes. Lightwave communication equipment includes sources, modulators, transmission media, detectors, converters, integrated optic circuits, and related devices, used for generating and processing light waves. The term *optical communications* is oriented toward the notion of optical equipment, whereas the term *lightwave communications* is oriented toward the signal being processed.

light-year—1. The distance traveled by light in one year, or about 5,880,000,000,000 miles or 9,500,000,000,000 km, roughly 6 trillion miles (9.5 trillion kilometers). A parsec (parallax second) is equal to 3.26 light-years. Both are units of distance, not time.

limit bridge—A form of Wheatstone bridge used for rapid routine production testing. Conformity with tolerance limits, rather than exact value, is determined.

limit cycle—A mode of control system operation in which the controlled variable cycles between extreme limits, with the average near the desired value.

limited continuous word/speech—Voice recognition capability for certain sets of words uttered without pause (typically digits such as part numbers or postal zip codes), which can be trained into user-programmable

limiting—The restricting of the amplitude of a signal so that interfering noise can be kept to a minimum.

limiting resolution—In television, the number of TV lines per picture height that can just be resolved by visual inspection of a televised pattern. Wedge patterns are often used for this subjective test. These charts include five areas (center and four corners) for resolution measurement. Each area includes two identical sets of mutually orthogonal wedge patterns calibrated (up to 16) in hundreds of TV lines per picture height. 2. The details that can be distinguished on the television screen. Vertical resolution refers to the number of horizontal black and white lines that can be resolved in the picture height. Horizontal resolution refers to the black and white lines resolved in a dimension equal to the vertical height and may be limited by the video amplifier bandwidth.

limit of error—An accuracy index that indicates the expected maximum deviation of the measured value from the true value if all of the factors causing deviations act simultaneously and in the same direction.

limit ratio—The ratio of peak value to limited value.

limits—The minimum and maximum values specified for a quantity.

limit switch—1. A mechanically operated contact-making or contact-breaking device mounted in the path of a moving object and actuated by its passage. 2. An electromechanical device that uses changes in mechanical motion to control electrical circuits. It functions as the interlocking link between a mechanical motion and an electrical circuit. 3. A switch that is actuated by some part or motion of a machine or equipment to alter the electrical circuit associated with it.

line—1. In television, a single trace of the electron beam from left to right across the screen. The present United States standard is based on 525 lines to a complete picture. 2. A conductor of electrical energy. 3. The path of the moving spot in a cathode-ray tube. 4. A term used interchangeably for maxwell. 5. A row of actual or potential holes at right angles to the direction in which a punched tape advances. Line width is measured in terms of the maximum number of holes permissible, excluding the sprocket hole. 6. The interconnection between two electrical devices. Usually used with reference to a long run of interconnecting cable, as from a microphone to its tape-recorder input. 7. In communications, describes cables, telephone lines, etc., over which data is transmitted to and received from the terminal.

line advance—Also called line feed. The distance between the centers of the scanning lines.

line amplifier—1. An amplifier that supplies a program transmission line or system with a signal at a specified level. 2. Also called line stretcher. An amplifier, usually remotely powered, used in a trunk line in a distribution system to increase the strength of the signal in order to drive an additional length of cable. 3. Also called program amplifier. An amplifier for audio or video signals that feeds a transmission line. 4. An audio amplifier that is used to provide preamplification of an audio alarm signal before transmission of the signal over an alarm line. Use of an amplifier extends the range of signal transmission. 5. An amplifier that supplies an audio system or an audio long cable with a signal at a specified level, usually between -10 and $+4$ dBv (245 millivolts to 1.23 volts rms). 6. An amplifier inserted in any part of the transmission line following the downconverter to compensate signal losses caused by long lengths of coaxial cable or the insertion of passive devices such as splitters. Line amplifiers are also used when the signal must drive a number of television receivers.

line and trunk group—A group consisting of four-wire line circuits, incoming trunks from private automatic branch exchanges, and intertoll trunk groups.

linear—1. Having an output that varies in direct proportion to the input. 2. A ratio in which change in one of two related quantities is accompanied by a directly proportional change in the other.

linear acceleration—The rate of change in linear velocity.

linear accelerator—A device for speeding up charged particles such as protons. It differs from other accelerators in that the particles move in a straight line instead of in circles or spirals.

linear accelerometer—A transducer used to detect, measure, and record the rate of change in linear velocity of accelerative forces.

linear actuator—An actuator that produces mechanical motion from electrical energy.

linear amplification—Amplification in which the output is directly proportional to the input.

linear amplifier—1. An amplifier that operates on the linear portion of its forward transfer characteristic so that its output signal is always an amplified replica of the input signal. 2. Amplifier whose gain is constant for a wide variation in amplitude of input signal—i.e., output signal is proportional to input signal. 3. Amplifier that has linear control characteristics and negligible response time in the active bandwidth, provides a wide speed range, and usually requires minimal external circuitry to prevent instability caused by phase-shifted feedback from reactive loads. Linear amplifiers also generate little electrical noise.

linear array—1. An antenna array in which the elements are equally spaced and in a straight line. 2. A

multielement antenna in which individual dipole elements are arranged end to end.

linear circuit—1. A circuit in which the output voltage is approximately directly proportional to the input voltage; this relationship generally exists only over a limited range of signal voltages and often over a limited range of frequencies. 2. A circuit whose output is a continuous amplified version of its input. That is, the output is a predetermined variation of its input. 3. A circuit in which a proportional, or linear, relationship exists between the input and output. In manufacturers' circuit classifications the term often includes all analog circuits, both linear and nonlinear.

linear control—A rheostat or potentiometer having uniform distribution of graduated resistance along the entire length of its resistance element.

linear detection—Detection in which the output voltage is substantially proportionate to the input voltage over the useful range of the detector.

linear detector—A detector that produces an output signal directly proportionate in amplitude to the variations in amplitude (for AM transmission) or frequency (for FM transmission) of the rf input.

linear device—An amplifying-type analog device with a linear input/output relation, as opposed to a nonlinear digital device, which is either completely on or completely off over large ranges of input signals.

linear differential transformer—A type of electromechanical transducer that converts physical motion into an output voltage, the phase and amplitude of which are proportional to position. *See also* linear motion transducer.

linear distortion—Amplitude distortion in which the output and input signal envelopes are not proportionate, but no alien frequencies are involved.

linear electrical parameters of a uniform line—Frequently called the linear electrical constants. The series resistance and inductance, and the shunt conductance and capacitance, per length of a line.

linear electron accelerator—An evacuated metal tube in which electrons are accelerated through a series of small gaps (usually cavity resonators in the high-frequency range). The gaps are so spaced that, at a specific excitation frequency, the electrons gain additional energy from the electric field as they pass through successive gaps.

linear feedback-control system—A feedback-control system in which the relationship between the pertinent measure of the system signals is linear.

linear integrated circuit—Abbreviated LIC. 1. A circuit whose output is an amplified, linear version of its input or whose output is a predetermined variation of its input. A class of integrated circuits that process analog information expressed as voltages or currents. 2. An integrated circuit whose output remains proportional to the input level. Generally the term is taken to mean an analog IC, such as a voltage regulator, comparator, sense amplifier, driver, etc., as well as a linear amplifier. The operation of the circuit can be made nonlinear by connecting the basic linear amplifier to external circuit elements that have thresholds or other nonlinear characteristics.

linearity—1. The relationship existing between two quantities when a change in a second quantity is directly proportionate to a change in the first quantity. 2. Deviation from a straight-line response to an input signal. 3. The ability of a meter to provide equal angular deflections proportional to the applied current. Usually expressed as a percent of the full-scale deflection. 4. The relationship between the actual electrical energy input and the deflection of a meter pointer, as referenced to a

theoretical straight line. Linearity is often confused with tracking. 5. In a modulator, the ability to generate a modulation envelope that reproduces the modulating signal without distortion. 6. The state of an output that incrementally changes directly or proportionally as the input changes. 7. The closeness of a calibration curve to a specified straight line; the degree to which the output of a linear device is proportional to the input.

linearity control—A control that adjusts the variation of scanning speed through the trace interval.

linearity error—The deviation of a calibration curve from a specified straight line.

linear logarithmic intermediate-frequency amplifier—An amplifier used to avoid overload or saturation as a protection against jamming in a radar receiver.

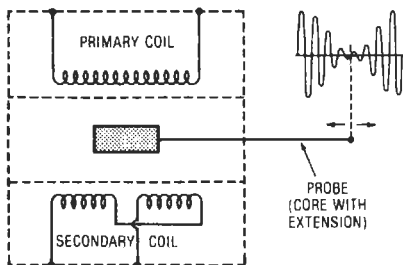

linear magnetostriction—Under stated conditions, the relative change of length of a ferromagnetic object in the direction of magnetization when the magnetization of the object is increased from zero to a specified value (usually saturation).

linear mobility—The synchronized incremental mobility of functionally transitional electrons in a semiconductor.

linear modulation—Modulation in which the amplitude of the modulation envelope (or the deviation from the testing frequency) is directly proportional to the amplitude of the modulating wave at all audio frequencies.

linear modulator—A modulator in which the modulated characteristic of the output wave is substantially linear with respect to the modulating wave for a given magnitude.

linear motion transducer—An instrumentation component that translates straightline (linear) mechanical motion into an ac analog that is usable as a feedback signal for control or display. A transformer-type device in which a movable magnetic core is displaced axially by the moving component being monitored. When the core is moved in one direction from the center of its stroke, the output voltage is in phase with the excitation voltage, and when the core is moved in the opposite direction from the center, the output voltage is 180° out of phase. At the center, the output voltage is (virtually) zero. In either direction from center, the voltage increases as a precise linear function of probe displacement. Thus, the output signal has two basic analog components: phase relationship with the excitation voltage, indicating the direction of travel; and voltage amplitude, indicating the length of travel.

Linear motion transducer.

linear polarization—The polarization of a wave radiated by an electric vector that does not rotate but that alternates so as to describe a line. Normally the vector is oriented either horizontally or vertically.

linear polarized wave—At a point in a homogeneous isotropic medium, a transverse electromagnetic wave whose electric field vector lies along a fixed line.

linear power amplifier—A power amplifier in which the output voltage is directly proportionate to the input voltage.

linear predictive coding—1. A method of analyzing and storing human speech by determining from speech patterns a description of a time-varying digital filter modeling the vocal tract. This filter is then excited by the proper type of input, depending on the sound to be synthesized. The output of the filter is passed through a digital-to-analog converter whose output is the desired synthetic speech. 2. Speech synthesis technique based in the frequency domain. The quality of the synthesis improves as the number of coefficients is increased. With ten coefficients, an approximate number of bits per second required for speech is 1200. 3. A parameter-encoding technique that models the human vocal tract with a digital filter whose controlling parameters change with time. Changes are based on previous speech samples.

linear programming—In computers, a mathematical method of sharing a group of limited resources among a number of competing demands. All decisions are interlocking because they must be made under a common set of fixed limitations.

linear pulse amplifier—A pulse amplifier that maintains the peak amplitudes of the input and output pulses in proportion.

linear rectification—The production, in the rectified current or voltage, of variations that are proportionate to variations in the input wave amplitude.

linear rectifier—A rectifier with the same output current or voltage waveshape as that of the impressed signal.

linear regression—A statistical function used when handling experimental data. It is especially used when performing an experiment to find a mathematical relationship between two variables. Linear regression is the name of the procedure that is used to find the line that best fits the set of data points that have been found experimentally. The procedure usually finds the equation of the straight line and also a parameter called the correlation coefficient, which indicates how well the data fits the line.

linear scan—A radar beam that traverses only one arc or circle.

linear scanning—Scanning in which a radar beam generates only one arc or circle.

linear sweep—In a television receiver, the movement of the spot across the screen at a uniform velocity during active scanning intervals.

Linearsyn—A linear displacement pickoff of the differential-transformer type consisting of a coil assembly and a movable magnetic core. Linear velocity units of high-coercive-force permanent magnetic cores that induce sizeable dc voltages while moving concentrically within shielded coils; the voltage varies linearly with the core velocity (Sanborn Co.).

line art—A computer-drawn graphic (without halftones) that can be clearly printed.

linear taper—A potentiometer that changes the resistance linearly as it is rotated through its range.

linear time base—In a cathode-ray tube, the time base in which the spot moves at a constant speed along the time scale. This type of time base is produced by application of a sawtooth waveform to the horizontal-deflection plates of a cathode-ray tube.

linear transducer—1. A transducer for which the pertinent measures of all the waves concerned are related by a linear function (e.g., a linear algebraic differential

or integral equation). 2. A transducer having its output at any given frequency proportional to the received input.

linear variable-differential transformer—*See* differential transformer.

linear varying parameter network—A linear network in which one or more parameters vary with time.

linear velocity transducer—A transducer that produces an output signal proportionate to the velocity of single-axis translational motion between two objects.

line-a-time printing—A type of computer output in which an entire horizontal row of characters is printed at the same time. *See also* line printer.

line balance—1. The degree to which the conductors of a transmission line are alike in their electrical characteristics with respect to each other, other conductors, and ground. 2. Impedance equal to that of the line at all frequencies (e.g., in terminating a two-wire line).

line-balance converter—A device used at the end of a coaxial line to isolate the outer conductor from ground.

line characteristic distortion—Distortion experienced in teletypewriter transmission when the presence of changing current transitions in the wire circuit affects the lengths of the received signal impulses.

line circuit—In a telephone system, the relay equipment associated with each station connected to a dial or manual switchboard. The term is also applied to a circuit for interconnecting an individual telephone and a channel terminal.

line coordinate—In a matrix, a symbol (normally at the side) identifying a specific row of cells and, in conjunction with a column coordinate, a specific cell.

line cord—Also called a power cord. A two-wire cord terminating in a two-prong plug at the end that goes to the supply, and connected permanently into a radio receiver or other appliance at the other end.

line-cord resistor—An asbestos-enclosed, wire-wound resistance element incorporated into a line cord along with the two regular wires. It lowers the line voltage to the correct value for the series-connected tube filaments and pilot lamps of a universal ac/dc receiver.

line diffuser—A circuit used to produce small vertical oscillations of the spot on the screen of a television monitor or receiver to make the line structure of the image less noticeable to an observer close to the screen.

line driver—1. An integrated circuit designed for transmitting logic information through long lines (normally at least several feet in length). 2. A buffer circuit with special characteristics (i.e., high current and/or low impedance) suitable for driving logic lines longer than normal interconnection length (greater than a few feet). It may have complementary (push-pull) outputs to work with the differential inputs of a line receiver. *See* line receiver. 3. A signal converter that conditions a digital signal to ensure reliable transmission over an extended distance.

linear variable-differential transformer — line fonts

line drop—A voltage loss occurring between any two points in a power or transmission line. Such a loss, or drop, is due to the resistance, reactance, or leakage of the line. An example is the voltage drop between a power source and load when the line supplying the power has excessive resistance for the amount of current.

line-drop signal—A signal associated with a subscriber line on a manual switchboard.

line-drop voltmeter compensator—A device using a voltmeter to enable it to indicate the voltage at some distant point in the circuit.

line equalizer—An inductance and/or capacitance inserted into a transmission line to correct its frequency-response characteristics.

line-equipment balancing network—A hybrid network designed to balance filters, composite sets, and other line equipment.

line-fault protection—A means of eliminating or reducing the effects of faults that occur on a transmission line such as a telephone circuit. Such faults include momentary losses of transmission due to signal outages and high noise levels.

line feed—*See* line advance.

line fill—The ratio of the number of main telephone stations connected to a line to the nominal main-station capacity of the same line.

line filter—1. A device containing one or more inductors and capacitors. It is inserted between a transmitter, receiver, or appliance and the power line to block noise signals. In a radio receiver, it prevents power-line noise signals from entering the receiver. In other appliances it prevents their own electrical noises from entering the power line. 2. A filter associated with a transmission line. In some applications, line filter may imply a filter used to separate the speech frequencies. In other applications, it may imply directional separation, etc.

line-filter balance—A network designed to maintain phantom-group balance when one side of the group is equipped with a carrier system. Since the network must balance the phantom group for voice frequencies only, its configuration is much simpler than the filter it balances.

linefinder—1. A switching mechanism that locates a calling telephone line among a group and connects it to a trunk, selector, or connector. 2. An electromechanical device that automatically line-feeds the platen of a printer to a predetermined line on a printed form.

linefinder shelf—A group (usually 20) of linefinders with the equipment required for routing the dial pulses from any of its associated calling telephones to a selector or connector.

linefinder switch—In a telephone system, an automatic switch for seizing the selector apparatus that provides the dial tone transmitted to the calling party.

line-focus tube—An X-ray tube in which the focal spot is roughly a line.

line fonts—Repetitive pattern used to give meaning to a line, e.g., solid, dashed, dotted, etc.

Line filter.

line frequency—Also called horizontal line frequency or horizontal frequency. 1. In television, the number of times per second the scanning spot crosses a fixed vertical line in the picture in one direction, including vertical-return intervals. 2. The nominal operating frequency of the power-line voltage used to supply operating power to instruments or equipment.

line-frequency regulation—The change in output (current voltage or power) of a regulated power supply for a specified change in line frequency.

line group—The frequency spectrum occupied by a group of carrier channels as they are applied to a transmission facility.

line hit—An electrical interference causing the introduction of spurious signals on a circuit.

line hydrophone—A directional hydrophone consisting of a single straight-line element, an array of adjacent electroacoustic transducing elements in a straight line, or the acoustic equivalent of such an array.

line impedance—The impedance measured across the terminals of a transmission line.

line input—Input channel of an amplifier designed to accept signal at a given level from a line at a specific impedance, usually 600 ohms.

line interlace—*See* interlaced scanning.

line leakage—Resistance existing through the insulation between the two wires of a telephone-line loop.

line lengthener—A device for altering the electrical length of a waveguide or transmission line, but not its physical length or other electrical characteristics.

line level—1. The level of a signal at a certain point on a transmission line. Usually expressed in decibels. 2. Based roughly on the “standardized” signal intensity sent over a telephone line, this term refers to any audio signal having a maximum intensity of between $\frac{1}{2}$ and $1\frac{1}{2}$ volts. Typically, this is the signal level put out by audio components that do not require preamplification (tuners, for instance).

line load—Usually a percentage of maximum circuit capability to reflect actual use during a period of time (e.g., peak-hour line load).

line loop—An operation performed over a communication line from an input unit at one terminal to output units at a remote terminal.

line loop resistance—Also called loop resistance. The metallic resistance of the pair of line wires that extend from a subscriber’s telephone to the central office (does not include the resistance of the telephone).

line loss—The total of the various energy losses in a transmission line.

line microphone—A directional microphone consisting of a single straight-line element, an array of adjacent electroacoustic transducing elements in a straight line, or the acoustical equivalent of such an array.

line noise—Noise originating in a transmission line.

line of force—1. Used in the description of an electric or magnetic field to represent the force starting from a positive charge and ending on a negative charge. 2. In an electric or magnetic field, an imaginary line in the same direction as the field intensity at each point. Sometimes called a maxwell when used as a unit of magnetic flux.

line of propagation—The path over which a radio wave travels through space.

line of sight—1. The distance to the horizon from an elevated point, including the effects of atmospheric refraction. The line-of-sight distance for an antenna at zero height is zero. 2. A straight line between an observer or radar antenna and a target. 3. An unobstructed, or optical, path between two points. 4. The radio-propagation

characteristic of a microwave. 5. The optical axis of a telescope or other observation system. The straight line connecting the object and the objective lens of the viewing device.

Line of sight, 3.

line-of-sight coverage—The maximum distance for transmission above the highest usable frequency. Radio waves at those frequencies do not follow the curvature of the earth and are not reflected from the ionosphere, but go off into space and are lost.

line-of-sight stabilization—In shipboard or airborne radar, compensating for the roll and pitch by automatically changing the elevation of the antenna in order to keep the beam pointed at the horizon.

line of travel—The path followed by an electromagnetic wave from one point to another

line oscillator—An oscillator in which the resonant circuit is a section of transmission line an integral number of quarter wavelengths in electrical length.

line output—Output channel of an amplifier designed to deliver signal at a given level to a line at a specific impedance, usually 600 ohms.

line pad—In radio broadcasting, a pad inserted between the final program amplifier and the transmitter to ensure a constant load on the amplifier.

line printer—1. In computers, a high-speed printer that produces an entire line at one time. All characters of the alphabet are contained around the rim of a continuously rotated disc, and there are as many discs as there are characters in the line. The computer momentarily stops the discs at the right characters for each line, and stamps out an impression in a fraction of a second. 2. A high-speed printer capable of printing simultaneously a complete line (80 to 120 characters) at once. It is capable of printing as many as 3000 lines a minute.

line protocol—1. A set of rules used to organize and control the flow of information between two or more stations connected by a common transmission facility. 2. A control program used to perform data-communication functions over network lines. Consists of both handshaking and line-control functions that move the data between transmit and receive locations.

line pulsing—A method of pulsing a transmitter by charging an artificial line over a relatively long period, and then discharging it through the transmitter tubes at a shorter interval determined by the line characteristics.

line radiator—A speaker enclosure that has several speakers arranged in a straight line to achieve a specific directional pattern.

line receiver—1. A circuit to receive signals from a line, usually driven by a line driver and having features such as differential input, Schmitt trigger, and the like. 2. Used in conjunction with a line driver to detect signals at the receiving end of a long line. *See also* line driver.

line regulation—1. The change in output (current, voltage, or power) of a regulated power supply for a specified change in line voltage. It may be stated as a percentage of the specified output and/or as an absolute value. 2. Percent change in output voltage at constant

junction temperature for a specified change in input voltage. This determines output accuracy of a regulator for changes in input voltage. 3. The maximum deviation of the output voltage of power supply in percent as the input voltage is varied from nominal to high line and nominal to low line. Output load and ambient temperature are held constant.

line relay—A relay activated by the signals on a line.

line sensor—A sensor with a detection zone that approximates a line or series of lines, such as a photoelectric sensor that senses a direct or reflected light beam.

line-sequential color-television system—A color-television system in which the individual lines of green, red, and blue are scanned in sequence rather than simultaneously.

line side—1. The contacts or terminals of an electrical device, designed to be connected to a conductor carrying line voltage from the source; the input side. 2. The side of equipment that “looks” toward the transmission path.

lines of force—In electric and magnetic fields, the electric and magnetic forces of repulsion or attraction, which are taken to follow certain imaginary lines radiating from the electric charge or the magnetic pole. (It is assumed that any unit electric charge or unit magnetic pole placed in the appropriate field will be acted upon so as to move in the direction of these imaginary lines.)

line spectra—Spectra that originate from atoms; they are composed of lines having irregular spacing and intensity.

line spectrum—The spectrum of a periodic, discrete signal consisting of one or more frequencies. For example, a square wave is characterized by a fundamental and odd-order harmonics.

line speed—1. The maximum rate at which signals may be sent over a given channel, usually expressed in bauds or in bits per second. 2. The rate at which text is transmitted over a line, expressed in bits per second.

line splitter—An active or passive device that divides a signal into two or more signals that contain all of the original information. A passive splitter feeds an attenuated version of the input signal to the output ports. An active splitter amplifies the input signal to overcome the splitter loss.

line-stabilized oscillator—An oscillator in which the frequency is controlled by using one section of a line as a sharply selective circuit.

line stretcher—1. A section of rigid coaxial line with telescoping inner and outer conductors that permit the section to be conveniently lengthened or shortened. 2. See line amplifier, 2.

line supervision—A means of determining that a transmission line is functional. Electronic protection of an alarm line accomplished by sending a continuous or coded signal through the circuit. A change in the circuit characteristics, such as a change in impedance due to the circuit's having been tampered with, will be detected by a monitor. The monitor initiates an alarm if the change exceeds a predetermined amount.

line switcher—Direct-current power supply that directly converts the ac line voltage to a lower dc value using switching techniques. Line switchers are highly efficient, but require care to contain electrical noise.

line switching—Also called circuit switching. A communications switching system that completes a circuit from sender to receiver at the time of transmission, as opposed to message switching.

line transformer—A transformer inserted into a system for such purposes as isolation, impedance matching, or additional circuit derivation.

line triggering—Triggering from the power-line frequency.

line unit—An electric device used in sending, receiving, and controlling the impulses of a teletypewriter.

line voltage—1. The voltage existing in a cable or circuit, such as at a wall outlet or other terminals of a power line system. The line voltage is usually between 115 and 120 volts, with 117 as an average, but may vary at times as much as 5 volts above or below the 115- and 120-volt limits. It is also the voltage existing in a cable or circuit. 2. The voltage supplied by an electrical power line or source, measured at the point of supply or sometimes at the point of utilization.

line-voltage regulator—A device that counteracts variations in the power-line voltage and delivers a constant voltage to the connected load.

line voltage transient protection—A device, or circuit, generally located on the line side of the control, that will divert or dissipate the energy contained in an abnormal line voltage spike. The purpose of this is to prevent possible control damage, especially to solid-state components, as a result of excessive voltage surges.

linguistic—Pertaining to language or its study, including its origin, structure, phonetics, etc.

linguistic variable—Common-language terms used to describe a fuzzy set, such as “hot,” “slow,” “very cold,” or “medium.”

link—1. A transmitter-receiver system connecting two locations. 2. In a digital computer, the part of a sub-program that connects it with the main program. 3. An interconnection. 4. In automatic switching, a path between two units of switching apparatus within a central office. 5. See channel. 6. A communication channel between two adjacent signaling points that provides a path for messages to travel. 7. To connect two elements in a data structure by using index variables or pointer variables.

linkage—1. A measure of the voltage that will be induced in a circuit by magnetic flux. It is equal to the flux times the number of turns linked by the flux. 2. A mechanical arrangement for transferring motion in a desired manner. It consists of solid pieces with movable joints. 3. In a computer, a technique used to provide interconnections for entry and exit of a closed subroutine to or from the main routine. 4. The instructions that connect one program to another, providing continuity of execution between the programs.

link blowing—An IC trimming technique that involves passing current pulses through points on the chip to open interconnection links between parallel resistors.

link circuit—A closed loop used for coupling purposes. It generally consists of two coils, each having a few turns of wire, connected by a twisted pair of wires or by other means, with each coil placed over, near, or in one of the two coils to be coupled.

link coupling—Inductive coupling between circuits. A coil in one circuit acts as the primary, and a coil in the second circuit as the secondary.

Link coupling.

linked list—A list formed by tying together (with pointers) several items on a disk.

linker—1. A program that connects small sections of a program together so they can run as a whole. 2. A utility program that ties different software modules into one entity.

link fuse—An unprotected fuse consisting of a short, bare wire between two fastenings.

linking loader—1. A computer program that takes program segments and places them one after the other in memory, adjusting jump and call instruction locations to match the new placement in the memory. 2. A routine that combines program segments and reassigns addresses to reflect the new memory locations. 3. A relocatable loader that links various object modules into a single load module, resolving external references in the process. This lets users load their programs into any memory area.

link neutralization—Neutralization of a tuned radio-frequency amplifier by means of an inductive coupling loop from the output to the input.

link transmitter—In broadcasting, a booster for a remote pickup or from a studio to main transmitter.

lin-log receiver—A radar receiver in which the amplitude response is linear for small-amplitude signals and logarithmic for large ones.

LiON—Abbreviation for lithium-ion.

lip microphone—A sensitive microphone that is placed in contact with the lip.

liquid-borne noise—Undesired sound characterized by fluctuations of pressure of a liquid about the static pressure as a mean.

liquid cooling—The use of a circulating liquid to cool components or equipment that heat up during operation.

liquid-core fiber—An optical fiber consisting of optical glass, quartz, or silica tubing filled with a higher-refractive-index liquid, such as tetrachloroethylene.

liquid-core optical fibers—Multimode straight fibers capable of transporting linearly polarized light with any incident polarization angle, and in which no form of internal stress can develop that could lead to birefringence.

liquid-crystal display—See LCD.

liquid crystals—Liquids that are doubly refracting and that display interference patterns in polarized light.

liquid-filled capacitor—A capacitor in which a liquid impregnant occupies substantially all of the case volume not required by the capacitor element and its connections. Space may be allowed for the expansion of the liquid under temperature variations.

liquid fuse unit—A fuse unit in which the fuse link is immersed in a liquid or the arc is drawn into the liquid when the fuse link melts.

liquid-impregnated capacitor—A capacitor in which a liquid impregnant is dominantly contained with the foil and paper winding, but does not occupy substantially all of the case volume not required by the capacitor element and its connections.

liquid laser—1. A laser in which the active material is in the liquid state. Present types employ a chelated rare-earth ion dissolved in an organic liquid. 2. A laser whose active medium is in liquid form, such as organic dye and inorganic solutions. Dye lasers are commercially available; they are often called organic dye or tunable dye lasers.

liquid rheostat—A rheostat consisting of metal plates immersed in a conductive liquid. The resistance is changed by raising or lowering the plates or the liquid level to vary the area of the plates contacting the liquid.

liquidus—The lowest temperature at which a metal or alloy is completely liquid.

liser—A microwave oscillator of very high spectrum purity. Its emission consists of right circularly polarized waves of two different cavity resonant frequencies.

LISP—Acronym for list processing. A high-level programming language used primarily for list processing, symbol manipulation, and recursive operations; it can handle many different data types, treat programs as data, and provide for the self-modification of the program as it is executing; generally considered a difficult language to learn.

Lissajous figures—Patterns produced on the screen of a cathode-ray tube when sine-wave signal voltages of various amplitude and phase relationships are applied to the horizontal- and vertical-deflection circuits simultaneously.

Lissajous figures.

list—Also called a chained or threaded list. A data structure in which each item of information has attached to it one or more links or pointers that refer to other items.

listening angle—The enclosed angle between the listener and the two speakers of a stereo reproducing system.

Listening angle.

listening post—The receiving terminus in a bugging or tapping operation. It may consist of recording equipment or a human operator or a combination of both.

listening sonar—See sonar.

list-processing language—A programming language that is widely used in artificial-intelligence research to manipulate categories or lists of items.

lithium—An alkali metal used in the construction of photocells and batteries.

lithium chloride sensor—Also called Dunmore cell. A hygroscopic element that has fast response, high accuracy, and good long-term stability and whose resistance is a function of relative humidity.

lithium-ion—Abbreviated LiON. A rechargeable battery technology that is able to produce considerably more charge than comparable size nickel-cadmium or nickel-metal hydride batteries.

lithography—A method of defining patterns for semiconductor device processing. Patterns are most frequently produced in thin films of materials called resists, which then resist a subsequent processing step being applied to an underlying material in accordance with that pattern. In typical semiconductor integrated-circuit fabrication, many different patterns are used to delineate features in a sequence of processing steps.

litz wire—Also called Litzendraht wire. A conductor composed of a number of fine, separately insulated strands that are woven together so that each strand successively takes up all possible positions in the cross section of the entire conductor. Litz wire gives reduced skin effect, hence, lower resistance to high-frequency currents.

live—1. A term applied to a circuit through which current is flowing. 2. Connected to a source of an electrical voltage. 3. Charged to an electrical potential different from that of the earth. 4. Reverberant, as a room in which there are reflections of sound. 5. A program that is transmitted as it happens, with no delay.

live cable test cap—A protective cap placed over the end of a cable to insulate the cable and seal its sheath.

live end—The end of a radio studio where the reflection of sound is greatest.

live parts—Metallic portions of equipment that are at a potential different from that of the earth.

live room—A room with a minimum of sound-absorptive material, such as drapes, upholstered furniture, rugs, etc. Because of the many reflecting surfaces, any sound produced in the room will have a long reverberation time.

LLTV—Also LLLTV and L³TV. Abbreviation for low-light television and low-light-level television. A CCTV system capable of operating with scene illumination less than 0.5 lumen/ft².

LNA—*See* low-noise amplifier.

LNB—Abbreviation for low-noise block downconverter. A microwave amplifier that converts a block of frequencies to a lower frequency. LNBs for satellite TV typically convert C- and Ku-band signals to a frequency band of 950 to 1450 MHz for input to the receiver.

LNC—*See* low-noise converter.

L-network—A network composed of two impedance branches in series. The free ends are connected to one pair of terminals, and the junction point and one free end are connected to another pair.

LO—*See* local oscillator.

load—1. The power consumed by a machine or circuit in performing its function. 2. A resistor or other impedance that can replace some circuit element. 3. The power delivered by a machine. 4. A device that absorbs power and converts it into the desired form. 5. The impedance to which energy is being supplied. 6. Also called work. The material heated by a dielectric or induction heater. 7. In a computer, to fill the internal storage with information obtained from auxiliary or external storage. 8. The resistance or impedance that the input of one device offers to the output of another device to which it is connected. *See* input impedance; termination, 1. 9. The circuit or transducer (e.g., speaker)

connected to the output of an amplifier. The source (e.g., pickup) is loaded by the amplifier's input impedance. 10. The electrical demand placed on a circuit or a system by the utilization equipment connected to it. Also, any piece of electrical utilization equipment of any given rating so connected. 11. To feed a program into a computer system. A common means of loading the program is via a form of magnetic media. The media is inserted into the media drive and the program read into the system's memory.

load and go—In a computer, an operation and compiling technique in which the pseudo language is converted directly to machine language and the program is then run without the creation of an output machine-language program.

load balance—*See* load division.

loadbreak connector—A connector designed to close and interrupt current on energized circuits.

load cell—1. Transducer that measures an applied load by a change in its properties, such as a change in resistance (strain-gage load cell), pressure (hydraulic load cell), etc. 2. A device that produces an output signal proportional to the applied weight or force.

load circuit—The complete circuit required to transfer power from a source to a load (e.g., an electron tube).

load-circuit efficiency—In a load circuit, the ratio between its input power and the power it delivers to the load.

load-circuit power input—The power delivered to the load circuit. It is the product of the alternating component of the voltage across the load circuit and the current passing through it (both root-mean-square values), times their power factor.

load coil—Also called a work coil. In induction heaters, a coil that, when energized with an alternating current, induces energy into the item being heated.

load curve—A curve of power versus time—i.e., the value of a specified load for each unit of the period covered.

load divider—A device for distributing power.

load division—Also called load balance. A control function that divides the load in a prescribed manner between two or more power sources supplying the same load.

loaded antenna—1. An antenna to which extra inductance or capacitance has been added to change its electrical (but not its physical) length. 2. An antenna employing a loading coil at its base or above its base to achieve the required electrical length using physically shorter elements.

Loaded antenna.

loaded applicator impedance—In dielectric heating, the complex impedance measured at the point of application with the load material properly positioned for heating and at the specified frequency.

loaded impedance—In a transducer, the impedance at the input when the output is connected to its normal load.

loaded line—1. A telephone line equipped with loading coils to add inductance in order to minimize amplitude distortion. 2. A transmission line that has lumped elements (inductance or capacitance) added at uniformly spaced intervals. Loading is used to provide a given set of characteristics to a transmission line.

loaded motional impedance—*See* motional impedance.

loaded Q—Also called the working Q . 1. The Q of an electric impedance when coupled or connected under working conditions. 2. In bandpass filters, a quantity that defines the percentages of 3-dB bandwidths. Numerically, it is equal to the center frequency divided by the 3-dB bandwidth.

loader—1. A program in a minicomputer that takes a program from some input or storage device and places it in memory at some address. Programs loaded by a loader are then ready to run. 2. A program that places a binary (machine language) program into successive core memory locations for execution. Some can replace relocatable addresses with absolute addresses. 3. A program that accepts input from an external device and places it in memory. The simplest loaders do no more than this. Other loaders include relocating loaders, linking loaders, and bootstrap loaders. 5. A program that controls peripheral device operation when reading programs for execution into system memory. 6. A program that transfers the object program from an external medium, such as paper tape, to the microcomputer random-access memory. Some loaders also convert a relocatable version of the object program to a loadable version. A program might originally be assembled to reside in the microcomputer memory starting at address zero. If the compiler or assembler has allowed the object program to be relocatable, the programmer can specify to the loader the program's new base address and the loader will modify all addresses accordingly in the object program. Another feature that is sometimes available is linkage editing, which establishes the linkages between different object programs that make reference to one another. Linkage editing requires both a compiler or assembler and a loader program that can communicate the appropriate information.

load factor—The ratio of average power demand, over a stipulated period of time, to the peak or maximum demand for that same interval.

load impedance—The impedance that the load presents to a transducer.

loading—1. In communication practice, the insertion of reactance into a circuit to improve its transmission characteristics. 2. Placing some material at the front or rear of a speaker so as to change its acoustic impedance and thus alter its radiation pattern.

loading coil—An inductor inserted into a circuit to increase its inductance and thereby improve its transmission characteristics.

loading-coil spacing—The line distance between the successive loading coils of a line.

loading disc—A metal disc placed on top of a vertical antenna to increase its natural wavelength.

loading error—The error introduced when more than negligible current is drawn from the output of a device.

loading factor—A number that represents the relative capacity of a gate for driving other gates or the relative load presented by a gate to the gate that drives it.

loading noise—Any unwanted signal caused by fluctuating contact resistance between the slider and the wire or film in a potentiometric transducer when current is drawn from the instrument.

loading routine—In a computer, a routine that, when in the memory, is able to read other information into the memory from external devices, tape, etc.

load isolator—A waveguide or coaxial device (usually ferrite) that provides a good energy path from a signal source to a load, but provides a poor energy path for reflections from a mismatched load back to the signal source.

load life—The ability of a device to withstand its full power rating over an extended period of time, usually expressed in hours.

load line—1. A straight line drawn across a series of plate-current plate-voltage characteristic curves on a graph to show how plate current changes with grid voltage when a specified plate-load resistance is used. 2. A line drawn on the collector characteristic curves of a transistor on which the operating point of the transistor moves as the collector current changes. Called a load line because the slope of the line depends on the value of the collector load resistance. 3. The line used to locate the operating point of the permanent magnet on the demagnetization curve. The slope of the shearing line is equal to the permeance coefficient.

load matching—In induction and dielectric heaters, adjustment of the load-circuit impedance so that the desired energy will be transferred from the power source to the load.

load-matching network—An electrical impedance network inserted between the source and the load to provide for maximum transfer of energy.

load-matching switch—In induction and dielectric heaters, a switch used in the load-matching network to alter its characteristics and thereby compensate for a sudden change in the load characteristics (such as in passing through the Curie point).

load mode—In some variable-word-length computers, data transmission in which certain delimiters are moved with the data (in contrast with move mode).

load point—Sometimes called BOT (beginning of tape). The point on a magnetic tape at which writing and reading begin. It is indicated by a reflective marker placed on the tape.

load regulation—1. For a constant-current supply, the change in the steady-state value of the output dc current due to a change in load resistance from a short-circuit current (zero resistance) to a value that results in the maximum rated output voltage. 2. For a constant-voltage supply, the change in the steady-state value of the output dc voltage due to a change in load resistance from an open-circuit condition (infinite resistance) to a value that results in the maximum rated output current. 3. The maximum deviation of the output voltage of a power supply in percent as the load is changed from minimum to maximum rated load. Input voltage is nominal value and ambient temperature is constant.

load resistor—A resistor connected in parallel with a high-impedance load so that the output circuit driving the load can provide at least the minimum current required for proper operation.

load sharing—A scheduling technique in multiprocessing systems whereby a task is executed by the next available processor. In order to make this technique operate successfully, all processors must be identical and have identical memory addressing capabilities.

load side—The contacts or terminals of an electrical device designed to be connected to conductors carrying voltage away from the device to the utilization equipment, or load, or another device; the output side.

loadstone—*See* lodestone.

load-transfer switch—A switch for connecting either a generator or a power source to one load circuit or another.

lobe—Also called directional, radiation, or antenna lobe. One of the areas of greater transmission in the pattern of a directional antenna. Its size and shape are determined by plotting the signal strength in various directions. The area with the greatest signal strength is known as the major lobe, and all others are called minor lobes.

lobe frequency—The number of times a lobing pattern is repeated per second.

lobe front—The major lobe of a directional antenna. The lobe in the direction of preferred reception or transmission.

lobe half-power width—In a plane containing the direction of the maximum energy of the lobe, the angle between the two directions in that plane about the maximum in which the radiation intensity is one-half the maximum value of the lobe.

lobe penetration—The penetration of the radar coverage of a station that is not limited by the pulse-repetition frequency, scope limitations, or the screening angle at the azimuth of penetration.

lobe switching—A form of scanning in which the maximum radiation or reception is periodically switched to each of two or more directions in turn.

lobing—The formation of maxima and minima at various angles of the vertical-plane antenna pattern by the reflection of energy from the surface surrounding the radar antenna. These reflections reinforce the main beam at some angles and tend to cancel it at other angles, producing fingers of energy.

local action—In a battery, the loss of otherwise usable chemical energy by currents that flow within regardless of its connections to an external circuit.

local alarm—An alarm that when activated makes a loud noise at or near the protected area or floods the site with light, or both.

local alarm system—An alarm system that when activated produces an audible or visible signal in the immediate vicinity of the protected premises or object. This term usually applies to systems designed to provide only a local warning of intrusion and not to transmit to a remote monitoring station. However, local alarm systems are sometimes used in conjunction with a remote alarm.

local area network—Abbreviated LAN. A data-communications system, usually owned by a single organization, that allows similar or dissimilar digital devices to talk to each other over a common transmission medium. Communications can also take place among diverse equipment types: mainframes, minicomputers, microcomputers, work processors, personal computers, intelligent terminals, workstations, printers, and disk drives. A local network provides such communications over a limited geographical area: a floor, a section of a building, an entire building or a cluster of buildings, or in a multistory building or factory complex. Distances can vary from a few hundred feet to several miles.

local battery—1. A battery made of single dry cells located at the subscriber's station. 2. A battery that actuates the recording instruments at a telegraph station (as distinguished from the battery that furnishes current to the line). 3. A telephone circuit power source, usually in the form of dry cells, located at the customer's end of the line.

local-battery telephone set—A telephone set that obtains transmitter current from a battery or other current supply circuit individual to the telephone set. The signaling current may be obtained from a local hand-operated generator or from a central power source.

local cable—A handmade cable form for circuit terminations at an attendant's switchboard, at unit equipment, and at other locations where wiring is routed inside the section or unit.

local central office—A central office arranged for termination of subscriber lines and provided with trunks for making connections to and from other central offices.

local channel—1. In private line services, that portion of a through channel within an exchange that is provided to connect the main station with an interexchange channel. 2. A standard broadcast channel in which several stations, with powers not in excess of 1000 watts daytime or 250 watts nighttime, may operate. 3. A channel connecting a communications subscriber to a central office.

local control—Also referred to as manual control. 1. Control of a radio transmitter directly at the transmitter, as opposed to remote control. 2. Manual control of a transmitter, with the control operator monitoring the operation on duty at the control point located at a station transmitter with the associated operating adjustments directly accessible. (Direct mechanical control, or direct wire control of a transmitter from a control point located on board an aircraft, vessel, or on the same premises on which the transmitter is located, is also considered local control.) 3. A method whereby a device is programmable by means of its local (front or rear panel) controls in order to enable the device to perform different tasks.

localizer—A radio facility that provides signals for guiding aircraft onto the center line of a runway.

localizer on-course line—A vertical line passing through a localizer. Indications of opposite sense are received on either side of the line.

localizer station—A ground radionavigation station that provides signals for the lateral guidance of aircraft with respect to the center line of a runway.

local loop—1. The access line from either a user terminal or a computer port to the first telephone office along the line path. 2. The teletype circuit containing a power source, the selector magnets, and a keyboard. This connection allows local copy on the teleprinter. 3. A telephone circuit that connects a subscriber's station equipment to the switching equipment in the telephone company local office.

local memory—Also called buffer RAM or sequence processor. A high-speed random-access memory used to store sequential data patterns that cannot be generated by a hardware pattern generator. Local memory often includes the capability to process data stores in RAM as if they were instructions, thereby modifying data in the buffer.

local oscillator—Abbreviated LO. Also called beat oscillator. 1. An oscillator used in a superheterodyne circuit to reproduce a sum or difference frequency equal to the intermediate frequency of the receiver. This is done by mixing its output with the received signal. 2. The oscillator whose output is mixed with the incoming signal in superheterodyne receivers to produce an intermediate frequency for signal processing (i.e., filtering, amplifying, detecting, etc.).

local-oscillator injection—An adjustment used to vary the magnitude of the local-oscillator signal that is coupled into the mixer.

local-oscillator radiation—Radiation of the fundamental or harmonics of the local oscillator of a superheterodyne receiver.

local-oscillator tube—The vacuum tube that provides the local-oscillator signal in a superheterodyne receiver.

local program—A program originating at and released through only one broadcast station.

local side—The connections from a data terminal to input-output devices.

local trunk—A trunk between local and long-distance switchboards, or a trunk between local and private branch exchange switchboards.

location—1. A unit-storage position in the main or secondary storage of a computer. 2. A storage position in memory.

location counter—In the control section of a computer, a register that contains the address of the instruction currently being executed.

lock—1. To terminate the processing of a magnetic tape in a manner such that the contents of the tape are no longer accessible. 2. To synchronize or become synchronized with; follow or control precisely, as in frequency, phase, motion, etc., used with on, onto, in, etc.

lock byte—An entity used to represent a resource in synchronization schemes; also termed a semaphore.

locked groove—Also called concentric groove. The blank and continuous groove in the center, near the label, of a disc record. It prevents the needle from traveling farther inward, onto the label.

locked-rotor current—In a motor, the steady-state current taken from the line while the rotor is locked and the rated voltage (and frequency in alternating-current motors) is applied to the motor.

locked-rotor torque—Also called static torque. 1. The minimum torque a motor will develop at rest, for all angular positions of the rotor, when the rated voltage is applied at rated frequency. 2. Motor torque at zero speed.

lock-in—1. The term used when a sweep oscillator is in synchronism with the applied sync pulse. 2. The shifting and automatic holding of one or both of the frequencies of two oscillating systems that are coupled together, so that the two frequencies have the ratio of two integral numbers.

lock-in amplifier—A form of synchronous detector having a balanced amplifier in which the signal is applied to the grids of two tubes as the control signal is applied to their plates or another grid. The difference of their output currents is then measured.

locking—1. Controlling the frequency of an oscillator by means of an applied signal of constant frequency. 2. Automatic following of a target by a radar antenna. 3. Pertaining to code extension characters that indicate a change in the interpretation of an unspecified number of subsequent characters.

locking circuit—*See* holding circuit.

locking-in—In two oscillators that are coupled together, the shifting and automatic holding of one or both of their frequencies so that the two frequencies are in synchronism (i.e., have the ratio of two integral numbers).

locking-out relay—An electrically operated hand-reset or electrically reset device that functions to shut down and hold an equipment out of service on the occurrence of abnormal conditions.

locking relay—*See* latch-in relay.

lock-in range—*See* tracking range.

lock-on—1. The instant at which radar begins to track a target automatically. 2. Signifies that a tracking or target-seeking system is continuously and automatically tracking a target in one or more coordinates.

lock-on range—The range from a radar to its target at the instant when lock-on occurs.

lockout—1. In a telephone circuit controlled by two voice-operated devices, a condition in which excessive local circuit noise or continuous speech from either or both subscribers results in the inability of one or both subscribers to get through. 2. *See* receiver lockout system. 3. Mechanical function whereby not

more than one switch station can be fully depressed simultaneously—for switches with interlock, nonlock, or pushlock/push-release mechanical functions.

lock range—The range of frequencies over which a phase-locked loop will remain locked on. The related tracking, or hold-in, range refers to how much the loop frequency can deviate from the center frequency, and is one-half the lock range.

lock shaft—A mechanical locking arrangement to prevent rotation of an adjustment after it has once been set.

lockup—Electromechanical function whereby switch stations are immobilized by operation (either actuating or releasing) of a solenoid (sometimes manually). Actuated switch stations cannot be released, and unactuated switch stations cannot be actuated until lockup is released. Lockup release can be accomplished locally or remotely.

lock-up relay—A relay that is locked in the energized position magnetically or electrically rather than mechanically.

loctal base—*See* loktal base.

lodar—Also called lorad. A direction finder that compensates for night effect by observing the distinguishable ground- and sky-wave loran signals on a cathode-ray oscilloscope and positioning a loop antenna to obtain a null indication of the more suitable components.

lodestone—Also spelled loadstone. A natural magnet consisting chiefly of a magnetic oxide of iron called magnetite.

lodex—A Hitachi trade name for permanent magnets that consist of elongated, single-domain iron cobalt particles dispersed in a lead matrix. The fine-particle magnets and binder are mixed in powder form and then pressed to final shape.

Lodge antenna—A counterpoise antenna that consists of a vertical dipole provided with horizontal top and bottom plates or screens, the lower plate or screen being spaced from the ground. Other versions include the bow-tie antenna, in which two narrow triangular plates are connected at their smaller ends by a coil, and the umbrella antenna, in which the end plates are conical and made up of wires.

Loftin-White circuit—A type of direct-coupled amplifier.

log—1. A listing of radio stations and their frequency, power, location, and other pertinent data. 2. A record of the station with which a radio station has been in communication. Amateur radio operators, as well as all commercial operators, are required by law to keep a log. 3. At a broadcast station, a detailed record of all programs broadcast by the station. 4. At a broadcast transmitter, a record of the meter readings and other measurements required by law to be taken at regular intervals. 5. Abbreviation for logarithm.

logarithmic amplifier—An amplifier whose output is a logarithmic (as opposed to linear) function of its input.

logarithmic converter—A device designed to convert linear change in the light state at input to logarithmic data at output.

logarithmic curve—A curve on which one coordinate of any point varies in accordance with the logarithm of the other coordinate of the point.

logarithmic decrement—1. For an exponentially damped alternating current, the natural logarithm of the ratio of the first to the second of two successive amplitudes having the same polarity. 2. *See* damping ratio, 2.

logarithmic fast time constant—A constant false alarm rate system in which a logarithmic intermediate-frequency amplifier is followed by a fast time constant circuit.

logarithmic horn—A horn whose diameter varies logarithmically with the length.

logarithmic scale—A scale on which the various points are plotted according to the logarithm of the number with which the point is labeled.

logarithmic scale meter—A meter having deflection proportional to the logarithms of the applied energies.

logger—An instrument that automatically scans certain quantities in a controlled process and records readings of the values of these quantities for future record.

logging—Recording data, such as error events or transactions, for future reference.

logic—Also called symbolic logic. 1. The science dealing with the basic principles and applications of truth tables, switching, gating, etc. *See* logical design. 2. A mathematical approach to the solution of complex situations by the use of symbols to define basic concepts. The three basic logic symbols are AND, OR, and NOT. When used in Boolean algebra, these symbols are somewhat analogous to addition and multiplication. 3. In computers and information-processing networks, the systematic method that governs the operations performed on the information, usually with each step influencing the one that follows. 4. The systematic plan that defines the interactions of signals in the design of a system for automatic data processing. 5. Circuitry designed to enhance separation between a matrix disc's recovered channels in a quadraphonic sound system. Such circuits monitor the four decoded channels and adjust the decoder dynamically to favor the main, or dominant, channel. 6. A mathematical arrangement using symbols to represent relationships and quantities, handled in a microelectronic network of switching circuits, or gates, which perform certain functions; also, the type of gate structure used in part of a data processing system.

logical choice—In a computer, the correct decision where alternatives or different possibilities are open.

logical comparison—In computers, the consideration of two items to obtain a yes (1) if they are the same with regard to some characteristic, or a no (0) if they are not.

logical decision—1. In a computer, the operation by which alternative paths of flow are selected depending on intermediate program data. 2. The ability of a computer to make a choice between alternatives; basically, the ability to answer yes or no to certain fundamental questions concerning equality and relative magnitude.

logical design—1. The preplanning of a computer or data-processing system prior to its detailed engineering design. 2. The synthesizing of a network of logical elements to perform a specified function. 3. The result of 1 and 2 above, frequently called the logic of the system, machine, or network.

logical diagram—In logical design, a diagram that represents logical elements and the interconnection between them, without necessarily including construction or engineering details.

logical element—In a computer or data-processing system, the smallest building blocks that operators can represent in an appropriate system of symbolic logic. Typical logical elements are the AND gate and the flip-flop.

logical flowchart—A detailed, graphical presentation of workflow in its logic sequence; often, the built-in operations and characteristics of a given machine, with types of operations indicated by symbols.

logically equivalent circuits—Logic circuits that perform the same function even though details of the circuits differ.

logical manipulation—Performing functions of AND, OR, exclusive OR, complementing, or rotating data in registers or in memory.

logical 1—The opposite of logical 0.

logical operations—Those operations considered to be nonarithmetical, such as selecting, searching, sorting, matching, and comparing.

logical state—Signal levels in logic devices are characterized by two stable states—the logical 1 state and the logical 0 state. The designation of the two states is chosen arbitrarily. Commonly the logical 1 state represents an on signal and the 0 state represents an off signal.

logical threshold voltage—At the output of a logic device, the voltage level at which the following logic device switches states.

logical 0—One of the two values of a binary digit signal. If the signal is a voltage, logical 0 usually is the lower of the two voltage levels.

logic analyzer—1. An instrument to monitor a number of test points to aid in troubleshooting. 2. An instrument that displays data or timing diagrams for designing, debugging, and troubleshooting digital equipment. 3. Equipment that displays program timing and response signals. The trigger is normally a match with a specified bit pattern, or a signal that fills the logic analyzer's buffer. Individual probes that can be attached to any desired signal line greatly enhance the analyzer's power. 4. An instrument that checks levels and/or timing of digital data.

logic array—An integrated device in which 50 or more circuits are integral to a single silicon chip. In addition, the circuits are interconnected on the chip to form some electronic function at a higher level of organization than a single circuit. Logic arrays are constructed by the unit cell method, in which a simple circuit (or function) is repeated many times on a slice. The interconnection pattern for converting groups of cells into large functions is determined after cell probe tests are completed. Each interconnection pattern may be unique to a single slice. In general, logic arrays are characterized by multiple levels of metallization to effect the large-scale function.

logic circuit—1. A circuit (usually electronic) that provides an input-output relationship corresponding to a Boolean-algebra logic function. 2. An electronic device or devices used to govern a particular sequence of operations in a given system.

logic devices—Digital components that perform logic functions. They can gate or inhibit signal transmission in accordance with the application, removal, or combination of input signals.

logic diagram—1. In logical design, a diagram representing the logical elements and their interconnections, but not necessarily their construction or engineering details. 2. A pictorial representation of interconnected logic elements using standard symbols to represent the detailed functioning of electronic logic circuits. The logic symbols in no way represent the types of electronic components used, but represent only their functions. 3. A drawing that depicts the multistate device implementation of logic functions with logic symbols and supplementary notation, showing details of signal flow and control, but not necessarily the point-to-point wiring. 4. A drawing that represents the logic functions AND, OR, NOT, etc.

logic element—1. A device that performs a logic function; a gate or flip-flop, or in some cases a combination of these devices treated as a single entity. 2. Symbol that has logical meaning. May also be called a logic symbol, e.g., gate, flip-flop, etc.

Logic diagram.

logic family—Group of digital integrated circuits sharing a basic circuit design with standardized input-output characteristics.

logic function—1. A means of expression of a definite state or condition in a magnetic amplifier, relay, or computer circuit. 2. One of the Boolean algebra functions AND, OR, and NOT, or a combination of these.

logic ground—A level that is used as a reference for digital signals in a system. Not necessarily at the same potential as earth or safety ground.

logic instruction—An instruction for execution of an operation defined in symbolic logic, such as AND, OR, NOR, or NAND.

logic level—1. One of two possible states, zero or one. 2. The voltage magnitude associated with signal pulses representing logical 1s and 0s in binary computation.

logic module—Circuit element comprising logic gates (AND, OR, NOT) and variations (NAND, NOR). Used in the design of binary arithmetic circuits, Boolean logic arrangements, etc.

logic-state analyzer—1. A test instrument that synchronously captures and displays data valid at a system's clock edge. It traces the flow of digital data and, hence, is said to work in the data domain. 2. An instrument used to track state flow and record state sequences occurring during program execution. It can reveal errors in software execution.

logic swing—The difference in voltage between the voltage levels for 0 and 1 in a binary logic circuit.

logic switch—A diode matrix or other switching arrangement that can direct an input signal to a selected one of several outputs.

logic symbol—A symbol used to represent a logical element on a graph.

logic system—1. A group of interconnected logic elements that act in combination to perform a relatively complex logic function. 2. Programming-recording system constructed of solid-state modules based on series of binary logic (go/no go) components.

logic timing analyzer—A test instrument that captures information that is asynchronous to a system's clock and displays the relative timing relationships of the traditional time domain. (Some logic analyzers display both data and timing diagrams.)

login—1. The account name used to gain access to a computer system. The account name (in contrast to the password) is not secret. 2. The act of entering into a computer system.

log/linear preamplifier—A preamplifier whose electrical output is proportional to the common logarithm of the input, but which can be switched to a different mode wherein the output is proportional to the input. Any amplifier whose transfer characteristic or calibration curve can be arbitrarily switched from the $y = A \log x$ form to the form $y = Ax$ (where y is the output and x is the input).

log on—A mechanism by which a computer system user identifies himself or herself and gains access to system facilities.

log-periodic antenna—A type of directional antenna that achieves its wideband properties by

geometric iteration. The radiating elements and the spacing between elements have dimensions that increase logarithmically from one end of the array to the other so that the ratio of element length to element spacing remains constant.

log receiver—A receiver in which the output amplitude is proportional to the logarithm of the input amplitude.

log scan—A spectrum display in which the frequency axis is calibrated logarithmically.

loktal base—Also spelled loctal. An eight-pin base for small vacuum tubes. It is designed so that it locks the tube firmly in a corresponding eight-hole socket. Unlike in other tubes, the pins are sealed directly into the glass envelope.

loktal tube—Also spelled loctal. A vacuum tube with a loctal base.

long base-line system—A system in which the distance separating ground stations approximates the distance to the target being tracked.

long-distance loop—A line that connects a subscriber's station directly to a long-distance switchboard.

long-distance navigational aid—A navigational aid usable beyond radio line of sight.

long-distance xerography—A facsimile system at the receiving terminal of which a lens projects a cathode-ray image onto the selenium-coated drum of a xerographic copying machine; a cathode-ray scanner is employed at the microwave transmitting terminal.

longevity—The normal operating lifetime of a piece of equipment, usually considered to be the period in which its failure rate is acceptably low and essentially constant.

longitudinal chromatic aberration—A lack of sharpness in the image because different colors come to a focus at different distances from the lens.

longitudinal circuit—A circuit in which one conductor is a telephone wire (or two or more wires in parallel) and the return is through the earth or any other conductors except those taken with the original wire or wires to form a metallic telephone circuit.

longitudinal coils—The coils that are used in transmission lines to suppress longitudinal currents.

longitudinal current—A current that flows in the same direction in both wires of a parallel pair. The earth is its return path.

longitudinal magnetization—In magnetic recording, magnetization of the recording medium in a direction essentially parallel to the line of travel.

longitudinal parity—Parity associated with bits recorded on one track in a data block to indicate whether there is an even or odd number of bits in the block.

longitudinal redundancy—In a computer, a condition in which the bits in each track or row of a record do not total an even (or odd) number. The term is generally used to refer to records on magnetic tape, and a system can have either odd or even longitudinal parity.

longitudinal wave—A wave in which the direction of displacement at each point in the medium is perpendicular to the wavefront, as, for example, in a sound wave propagated in air.

long line—A communication line spanning a long distance relative to the local loop.

long-line effect—An effect that occurs when an oscillator is coupled to a transmission line with a serious mismatch. Oscillation may be possible at two or more frequencies, and the oscillator jumps from one side of these frequencies to another as its load changes.

long-lines engineering—Engineering with the objective of developing, modernizing, or expanding long-haul, point-to-point communications facilities that use radio, microwave, fiber optics, or wire circuits.

long-nose pliers—Pliers with long, narrow holding jaws suitable for wrapping wire around closely spaced terminals.

long-persistence screen—A fluorescent and phosphorescent screen in which the light intensity of its spots does not immediately die out after the beam has moved on. The generation of light at the instant the electron beam strikes the screen is due to fluorescence; the light that persists after the beam has moved on is due to phosphorescence. The time of persistence varies with the type of tube employed and the coating of the screen.

long-play record—Abbreviated LP record. Also called a microgroove record. A 10- or 12-inch (25.4- or 30.5-cm) record or transcription with finely cut grooves that give it a long playing time.

long-pull magnet—An electromagnet designed to exert a practically uniform pull for an extended range of armature movement. It consists of a conical plunger moving up and down inside a hollow core.

long-range navigation—See *loran*.

long-range radar—A radar installation capable of detecting targets 200 or more miles (320 km) away.

long-reach mike—See *shotgun mike*.

long shunt—A shunt field connected across the series field and the armature, instead of directly across the armature alone, of a motor or generator.

long-tailed pair—A two-tube circuit in which decreased plate current through one tube results in increased plate current through the other tube, and vice versa.

long-term stability (or long-term instability)—The slow changes in average frequency arising from changes in an oscillator. Statements of long-term stability for quartz oscillators often term this characteristic *aging rate* and specify it as parts per day (fractional frequency change over 24 hours). For cesium standards, this term commonly refers to the total fractional frequency drift for the life of the cesium beam tube.

long throw—A method of speaker design in which the woofer moves freely through long excursions, providing excellent low-frequency response with low distortion.

long wave—Wavelengths longer than about 1000 meters. They correspond to frequencies above 300 kHz.

long-wire antenna—1. An antenna that has a length greater than one-half wavelength at the operating frequency. 2. A directional antenna consisting of a single straight wire whose length is several times greater than its operating wavelength.

look ahead—1. A feature of the CPU of a computer that allows the machine to mask an interrupt request until the following instruction has been completed. 2. A feature of adder circuits and ALUs that allows these devices to look ahead to see that all carries generated are available for addition.

lookthrough—1. In jamming, sporadic interruption of the emission for extremely short periods in order to monitor the victim signal. 2. When a set is being jammed, the monitoring of the desired signal during lulls in the jamming signals.

loom—A flexible nonmetallic tubing placed around insulated wire for protection.

loop—1. A complete electrical circuit. 2. In a computer, a series of instructions that are carried out repeatedly until a terminal condition prevails, e.g., until a predetermined count or other test is satisfied. 3. In automatic control, the path followed by command signals, which direct the actions to be performed, and feedback signals, which are returned to the command point to indicate what is actually happening. See also *closed loop*. 4. See *mesh*. 5. A length of tape having its ends spliced together to form an endless loop. Frequently used

by film and radio/TV sound departments for prolonged backgrounds of continual or repetitive sound effects. The loop is the basis of the 8-track cartridge format. 6. A combination of one or more interconnected instruments arranged to measure or control a process variable, or both. 7. The two-wire circuit formed by a customer's telephone set, cable pair, and other conductors that connect it to the central office equipment. 8. An electric circuit consisting of several elements, usually switches, connected in series. 9. The curve or arc made by the wire between the attachment points at each end of a wire bond. 10. See *antinodes*.

loop actuating signal—The signal derived from mixing the loop input and loop feedback signals.

loop antenna—1. An antenna used in radio direction-finding apparatus and in some radio receivers. It consists of one or more loops of wire. 2. An antenna consisting of several turns of wire in the same plane so arranged that it encloses an area in the electromagnetic field.

Loop antenna.

loopback—A diagnostic procedure used for transmission devices. A test message is sent to a device being tested. The message is then sent back to the originator and compared with the original transmission. Loopback testing may be performed with a locally attached device or conducted remotely over a communications circuit.

loopback test—A test in which signals are looped from a test center through a data set or loopback switch and back to the test center for measurement. See also *busback*.

loop circuit—A communication circuit that more than two parties share. In teletypewriter application, all machines print all data entered on the loop.

loop control—The maintaining of a specified loop of material between two sections of a machine by automatically adjusting the speed of at least one of the driven sections.

loop counter—In a computer, a register used to implement high-speed loop branching, including simple instruction loops (test and decrement must also be performed in the same instruction).

loop current—Flow of dc in the local loop of a telephone circuit. Indicates that a telephone is in use.

loop dialing—A return-path dialing method in which pulses are sent out over one side of the interconnecting line or trunk and returned over the other side. This arrangement is limited to short-haul traffic.

loop difference signal—The output signal from a summing point of a feedback control loop. It is a specific type of loop actuating signal produced by a particular loop input signal applied to that summing point.

loop disconnect dialer—A circuit used to convert ten-digit push-button telephone inputs to an output series of dialing pulses. This enables a push-button telephone to be connected into a telephone system that was designed to accept inputs from rotary-dial telephones only.

loop error—The desired value minus the actual value of the loop output signal.

loop error signal—The loop actuating signal, when it is the loop error.

loop feedback signal—The signal derived from the loop output signal and fed back to the mixing point for control purposes.

loop feeder—A feeder that follows along a circuit and distributes the voltage more evenly at different points.

loop gain—1. The total usable power gain of a carrier terminal or two-wire repeater. Because any closed system tends to sing (oscillate), its usable gain may be less than the sum of the enclosed amplifier gains. The maximum usable gain is determined by—and cannot exceed—the losses in the closed path. 2. The increase in gain observed when the feedback path of an amplifier is opened, but with all circuit loads intact. 3. In an operational amplifier circuit, the product of the transfer characteristics of all of the elements (active or passive) encountered in a complete trip around the loop, starting at any point and returning to that point.

loop height—A measure of the deviation of the wire loop from the straight line between the attachment points of a wire bond. Usually it is the maximum perpendicular distance from this line to the wire loop.

looping—Repetition of instructions at delayed speeds until a final value is determined (as in a weight scale indication). The looped repetitions are usually frozen into a ROM memory location and then jumped when needed. Looping also occurs when the CPU of a computer is in a wait condition. *See also* loop through.

looping-in—Wiring method that avoids tee joints by carrying the conductor or cable to and from the point to be supplied.

loop input signal—An external signal applied to a feedback control loop.

loop-mile—The length of wire in a mile of two-wire line.

loop noise bandwidth—A phase-locked loop property related to damping and natural frequency that describes the effective bandwidth of the received signal. Noise and signal components outside this band are highly attenuated.

loop output signal—The controlled signal extracted from a feedback control loop.

loop pulsing—Also called dial pulsing. The regular, momentary interruption of the direct-current path at the sending end of a transmission line.

loop resistance—The total resistance of two conductors measured at one end (conductor and shield, twisted pair, conductor and armor, etc.). *See also* line loop resistance.

loop return signal—The signal returned, via a feedback control loop, to a summing point in response to a loop input signal applied to that summing point. The loop return signal is a specified type of loop input signal and is subtracted from it.

loopstick antenna—*See* ferrite-rod antenna.

loop test—A method of locating a fault in the insulation of a conductor when the conductor can be arranged to form part of a closed circuit.

loop through—Also called looping. The method of feeding a series of high-impedance circuits (such as multiple monitor displays in parallel) from a pulse or video source with a coaxial transmission line in such a manner that the line is bridged (with minimum length stubs) and that the last unit properly terminates the line in its characteristic impedance. This minimizes discontinuities or reflections on the transmission line.

loop transfer function—The transfer function of the transmission path. It is formed by opening and properly terminating a feedback loop. *See also* transfer function.

loose coupler—An obsolete tuning system consisting of two coils, one inside the other. Coupling was varied over a wide range by sliding one coil over the other.

loose coupling—Also called weak coupling. 1. In resonant systems, a degree of coupling that is considerably less than critical coupling. Hence, there is very little transfer of energy. 2. Coupling between two circuits so that (a) little power is transferred from one to the other and (b) an impedance change in one circuit has little effect on the other circuit.

LORAC—A trademark of Seismograph Service Corp. for a specific navigation system that determines a position fix by the intersection of lines of position. Each line is defined by the phase angle between two heterodyne beat-frequency waves. One wave is the beat frequency between two cw signals from two widely spaced transmitters. The other is a reference wave of the same frequency and is obtained by deriving the heterodyne beat of the same two cw signals at a fixed location and transmitting it, via a second radio-frequency channel, to the receiver being located.

lorad—*See* lodar.

loran—A contraction of long-range navigation. 1. A navigation aid sending out pulses at radio frequencies between 1800 and 2000 kHz. It defines lines of position that are based on the differences in travel time between radio waves from a master and a slave station. Airborne equipment utilizes a picture tube and measuring circuits to determine the time differences and relate them to time-difference lines drawn on a map. A navigation fix is established by the intersection of two or more lines of position. 2. A long-range electronic navigation system that uses the time divergence of pulse-type transmission from two or more fixed stations.

loran C—A hyperbolic navigation system that relies on the stability of electromagnetic propagational characteristics at a frequency of 100 kHz. Each loran-C station operates in a pulse mode in such a way that no two stations can be received simultaneously. During the transmission period of the master station, both slave stations remain silent. After a fixed delay time, slave X will transmit a similar pulse. After a second delay, slave Y will transmit a pulse.

loran D—A tactical loran system that employs the coordinate converter of loran C and can be operated in conjunction with inertial systems on board aircraft, without dependence on ground facilities and without radiation of rf energy that could reveal the location of the aircraft.

loran line—A line of position on a loran chart where each line is the locus of points, the distances from two fixed stations of which differ by a constant amount.

loran station—A radionavigational land station transmitting synchronized pulses.

loran tables—Tables giving terrestrial coordinates (latitude and longitude) of loran lines of position and values of the skywave correction.

Lorentz force—The force exerted by an electric field and a magnetic field on a moving electric charge.

Lorentz force equation—An equation relating the force on a charged particle to its motion in an electromagnetic field.

loss—1. A decrease in power suffered by a signal as it is transmitted from one point to another. It is usually expressed in decibels. 2. Energy dissipated without accomplishing useful work. 3. A reduction in signal level or strength, usually expressed in decibels.

loss angle—The complement of the phase angle of an insulating material.

lossier—A circuit having less power in the output as compared with the power applied to the input. This term

is particularly applicable to mixers; a crystal mixer is a losser.

losser circuit—A resonant circuit having sufficient high-frequency resistance to prevent sustained oscillation at the resonant frequency.

Lossev effect—The resultant radiation when charge carriers recombine after being injected into a forward-biased pn or pin junction.

loss factor—See loss index.

loss index—Also called loss factor. 1. The product of the dielectric constant and the loss tangent. It is a measure of the power loss per cycle and receives extensive use in microwave and dielectric heating applications. 2. The product of the power factor and the dielectric constant. 3. The characteristic that determines the rate at which heat is generated in an insulating material. It is equal to the dielectric constant times the power factor.

lossless line—A theoretically perfect line—i.e., one that has no loss and hence transmits all the energy fed to it.

loss modulation—See absorption modulation.

loss tangent—Also called dielectric dissipation factor. The decimal ratio of the irrecoverable to the recoverable part of the electrical energy introduced into an insulating material by the establishment of an electric field in the material.

lossy—1. Insulating material that dissipates more than the usual energy. 2. Of, like, or made of an insulating material capable of damping out an unwanted mode of oscillation while having little effect on a desired mode.

lossy attenuator—A length of waveguide made from some dissipative material and used to deliberately introduce transmission loss.

lossy cable—A single-circuit cable (frequently of coaxial construction) deliberately constructed to have high transmission loss so that it can be used as an attenuator, an artificial load, or a termination.

lossy line—1. A transmission line designed with high attenuation. 2. A transmission line, usually a coaxial cable, designed to have a very high transmission loss per unit length.

lot—A group of similar components that have been either all manufactured in a continuous production run from homogeneous raw materials under constant process conditions or assembled from more than one production run and submitted for random sampling and acceptance testing. Specifically, a quantity of material all of which was manufactured under identical conditions and assigned an identifying lot number.

lot tolerance percent defective—Abbreviated LTPD. A statistically defined quality level, in percent defective that is rejected on an average 90 percent of the time. Thus, a lot that is truly 5 percent defective is rejected 90 percent of the time when a 5-percent LTPD is used.

Lotus 1-2-3—A flexible, easy to use spreadsheet program for IBM PCs and compatibles. It combines graphics, spreadsheet functions, and data management.

loudness—1. A measure of the sensitivity of human hearing to the strength of sound. Scaled in sones, it is an overall single evaluation resulting from calculations based on several individual band-index values. 2. Generally synonymous with volume, which is the intensity of perceived sound.

loudness compensation—1. A variety of equalization applied to a signal according to its volume in order to compensate for the tendency of the ear to change frequency responses at different listening levels. 2. A form of equalization, coupled with the volume control, that progressively emphasizes low frequencies (and sometimes also high frequencies) relative to the middle frequencies

as the volume is reduced. Intended to correct for the human ear's natural loss of hearing sensitivity at the frequency extremes when sound level is reduced, and thus to preserve proper frequency balance at different listening volume levels.

loudness contour—A curve showing the sound pressure required at each frequency to produce a given loudness sensation to a typical listener.

loudness-contour selector—Abbreviated LCS. A circuit that alters the frequency response of an amplifier so that the characteristics of the amplifier will more closely match the requirements of the human ear.

loudness control—Also called compensated volume control. A combined volume and tone control that boosts the bass frequencies at low volume to compensate for the inability of the ear to respond to them. Some loudness controls provide similar compensation at the treble frequencies.

loudness level—The sound-pressure level of a 1000-Hz tone judged by a listener to be as loud as the sound under consideration. It is measured in decibels relative to 0.0002 microbar.

loudspeaker—See speaker.

loudspeaker dividing network—See dividing network.

loudspeaker impedance—See speaker impedance.

loudspeaker system—See speaker system.

loudspeaker voice coil—See speaker voice coil.

louver—The grille of a speaker.

love wave—A dispersive or frequency-sensitive surface effect that also decays exponentially with depth. Love waves consist of particle motion in the plane of the surface and normal to the direction of wave propagation. These are generated when a substrate is covered with a film of solid material whose thickness is considerably smaller than the wavelength.

low-angle radiation—Radiation that proceeds at low angles above the ground.

low band—Television channels 2 through 6, covering frequencies between 54 and 88 MHz.

low-capacitance contacts—A type of contact construction providing small capacitance between contacts.

low-capacitance probe—A test probe with very low capacitance. It is connected between the input of an oscilloscope and the circuit under observation.

Low-capacitance probe circuit.

low-corner frequency—The frequency at which the output of a resolver is 3 dB below the midfrequency value and the phase shift is 45°.

low-definition television—A television system employing less than 200 scanning lines per frame.

low earth orbit—See LEO.

low-energy circuit—Also called a dry circuit. A circuit application that functions at low voltage (i.e., approximately 10 volts or less) and low current (i.e., approximately 1 mA or less).

low-energy criterion—See Von Hippel breakdown theory.

low-energy material—See soft magnetic material.

lower pitch limit—The minimum frequency at which a sinusoidal sound wave will produce a pitch sensation.

lower sideband—1. The lower of two frequencies or groups of frequencies produced by the amplitude-modulation process. 2. In carrier transmission, the band of frequencies that is lower than the carrier frequency. It is the difference between the instantaneous values of the carrier frequency and the modulating frequency.

lowest effective power—The minimum product of the antenna input power in kilowatts and the antenna gain required for satisfactory communication over a particular radio route.

lowest useful frequency—Abbreviated LUF. The lowest frequency in the high-frequency radio band that can be used at a particular time of day for ionospheric propagation between two specified points.

lowest useful high frequency—In radio transmission, the lowest frequency effective at a specified time for ionospheric propagation of radio waves between any two points, excluding frequencies below several megahertz. It is determined by such factors as absorption, transmitter power, antenna gain, receiver characteristics, type of service, and noise conditions.

low filter—An audio circuit designed to remove low-frequency noises from the program material. Such noises include turntable rumble, tonearm resonance, etc.

low frequency—Abbreviated LF. The band of frequencies extending from 30 to 300 kHz (10,000 to 1000 meters).

low-frequency compensation—A technique for extending the low-frequency response of a broadband amplifier.

low-frequency distortion—Distortion effects that occur at low frequency. In television, generally considered as any frequency below the 15.75-kHz line frequency.

low-frequency impedance corrector—An electric network designed to be connected to a basic network, or to a basic network and a building network, so that the combination will simulate, at low frequencies, the sending-end impedance, including the dissipation, of a line.

low-frequency induction heater or furnace—A heater or furnace in which the charge is heated by inducing a current at the power-line frequency through it.

low-frequency loran—Also called hertz-matching loran. A modification of standard loran, with operation in the frequency range of approximately 100 to 200 kHz, for increased range over land and during daytime. Whereas the envelopes of the pulses are matched to obtain a line of position with ordinary loran, the hertz within the pulses are matched to provide a much more accurate fix with low-frequency loran.

low-frequency padder—In a superheterodyne receiver, a small adjustable capacitor connected in series with the oscillator tuning coil. During alignment it is adjusted to obtain correct calibration of the circuit at the low-frequency end of the tuning range.

low insertion force connector—See LIF connector.

low level—In digital logic, the more negative of the two binary-system logic levels. See also high level; negative logic; positive logic.

low-level contacts—Contacts that control only the flow of relatively small currents in relatively low-voltage circuits—e.g., alternating currents and voltages encountered in voice or tone circuits, direct current on the order of microamperes, and voltages below the softening

voltages on record for various contact materials (that is, 0.080 volt for gold, 0.25 volt for platinum, and the like). Also defined as the range of contact electrical loading where there can be no electrical (arc transfer) or thermal effects and where only mechanical forces can change the conditions of the contact interface. In general, loads below 5 volts dc and 10 milliamperes are considered low level.

low-level crossover network—A crossover network designed to operate at line levels and which is placed before the power amplifier(s); used in biamplified or triamplified speaker systems.

low-level modulation—1. The modulation produced in a system when the power level at a certain point is lower than it is at the output. 2. Modulation introduced at a low-level point in a system, before amplification.

low-level radio-frequency signal (tr, atr, and pre-tr tubes)—A radio-frequency signal with insufficient power to fire the tube.

low-level signal—Very small amplitudes serving to convey information or other intelligence. Variations in signal amplitude are frequently expressed in microvolts.

low-loss dielectric—An insulating material, such as polyethylene, that has a relatively low dielectric loss, making it suitable for transmission of radio frequency.

low-loss insulator—An insulator with high radio-frequency resistance and hence slight absorption of energy.

low-loss line—A transmission line with relatively low losses.

low-noise amplifier—Abbreviated LNA. A device that receives and amplifies the weak satellite signal reflected by a dish via a feed. C-band LNAs typically have noise characteristics quoted as noise temperatures rated in degrees Kelvin. Ku-band LNA noise characteristics are usually expressed as a noise figure in decibels.

low-noise block downconverter—Abbreviated LNB. A low-noise microwave amplifier and converter that downconverts a block or range of frequencies at once to an intermediate frequency range, such as 950 to 1450 MHz, 950 to 1750 MHz, or 950 to 2050 MHz.

low-noise cable—Cable configuration specially constructed to eliminate spurious electrical disturbances caused by capacitance changes of self-generated noise induced by either physical abuse or adjacent circuitry.

low-noise converter—Abbreviated LNC. A combination low-noise amplifier and remote downconverter housed in one weatherproof box.

low-noise tape—Magnetic tape with a signal-to-noise ratio 3 to 5 dB better than conventional tapes, making it possible to record sound—especially music with a wide frequency range—at reduced tape speeds without incurring objectionable background noise (hiss) and with little compromise of fidelity.

low order—The least significant half of a word. Usually bits 0–7 of a 16-bit word.

low-pass filter—1. A filter network that passes all frequencies below a specified frequency with little or no loss but discriminates strongly against higher frequencies. 2. Wave filter having a single transmission band extending from zero frequency up to some critical or cutoff frequency not infinite. 3. Filter that passes all frequencies below a certain cutoff point and attenuates all frequencies above that point.

Low-pass filter.

low-power Schottky TTL (LS-TTL) circuit—A relatively high speed and low-power transistor-transistor logic (TTL) circuit using metal/semiconductor diodes (Schottky diodes) to prevent transistors from saturating.

low print-through tape—Special magnetic recording tape significantly less susceptible to print-through (the transfer of signal from one layer to another), which results when tape is stored for long periods of time. These tapes are especially useful for speech master recording (making an original recording from which copies will be made) on professional-quality equipment.

low-rate discharge—The withdrawal of a small current from a cell or battery for long periods of time.

low-speed data rate—Transmission of data at any speed up to 150 bauds.

low state—The relatively less positive signal level used to assert a specific message content associated with one of two binary logic states.

low tension—British term for low voltage. Generally refers to the heater or filament voltage.

low-velocity scanning—The scanning of a target with electrons having a velocity below the minimum required to give a secondary-emission ratio of unity.

low-voltage protection—See undervoltage protection.

L-pad—A volume control that has practically the same impedance at all settings. It consists essentially of an L-network in which both elements are adjusted simultaneously.

L + R, L - R—The sum and difference signals of the two stereo channels; the L + R signal combines the signals of both channels in phase; the L - R signal combines them out of phase. By combining in suitable circuitry, L + R and L - R can be added to obtain 2L, the signal from one channel; L - R can be subtracted from L + R to obtain 2R, the signal from the other channel.

LP record—Abbreviation for long-playing record.

LSA diode—Limited space-charge accumulation diode. A microwave diode similar to the Gunn diode except that by avoiding the formation of charge bunches or domains, it achieves higher output power at frequencies determined by a microwave cavity that are several times greater than the transit-time frequency.

LSB—Abbreviation for least significant bit.

L-scan—See L-display.

LSD—Abbreviation for least significant digit.

LSI—Abbreviation for large-scale integration. Integrated circuits containing between 100 and 5000 gate equivalents, or 1000 to 16,000 bits of memory. Over the years, integration levels have progressed from SSI (small-scale integration), MSI (medium-scale integration), and LSI to today's ULSI (ultra large scale integration).

Integration levels

Integration type	Chip area (sq-mils)	No. of gates	Memory (bits)
SSI	<10 K	<10	—
MSI	10–25 K	10–100	<1000
LSI	25–100 K	100–5000	1–16 K
VLSI	>100 K	>5000	>16 K
ULSI	>1000 K	>50,000	>256 K

LTPD—Abbreviation for lot tolerance percent defective.

LUF—Abbreviation for lowest useful frequency.

lug—1. A device soldered or crimped to the end of a wire lead to provide an eye or fork that can be placed under the head of a binding screw. 2. A wire terminal. 3. An earlike projection of a terminal, to which an electrical connection can be made by soldering, crimping, or wrapping.

lumen—Letter symbol: lm. 1. The unit of luminous flux. It is equal to the flux through a unit solid angle (steradian) from a uniform point source of 1 candela (candle) or to the flux on a unit surface all points of which are at unit distance from a uniform point source of 1 candela. 2. A unit of light emitted from a point light source of 1 candle through a unit solid angle. All lamps are rated in their output in lumens of light.

lumen/ft²—A unit of incident light. It is the illuminance on a surface 1 square foot in area on which a flux of 1 lumen is uniformly distributed, or the illuminance at a surface all points of which are at a distance of 1 foot from a uniform source of 1 candela.

lumen-hour—A unit of the quantity of light delivered in 1 hour by a flux of 1 lumen.

lumen-second—The unit quantity of light equal to 1 lumen of luminous flux emitted for 1 second.

luminaire—1. A complete lighting unit comprising a lamp or lamps and the parts required to distribute the light, position and protect the lamps, and connect the lamps to the power supply. 2. A complete unit containing a light source, globe, reflector, housing, socket, and other necessary components for lighting.

luminaire efficiency—The ratio of luminous flux (lumens) emitted by a luminaire to that emitted by the lamp or lamps used therein.

luminance—1. The luminous flux emitted, reflected, or transmitted from the source. Usual units are the lumen per steradian per square meter, candle per square foot, meterlambert, millilambert, and footlambert. Formerly known as brightness. 2. In color television, the photometric quantity of light radiation. 3. The amount of light emitted or scattered by a surface, usually measured in footlamberts. One footcandle falling upon a perfectly diffusing white surface with no loss would produce 1 footlambert. 4. The luminous flux per unit solid angle emitted per unit projected area of a source. 5. The photometric equivalent of brightness. It is based on measurements made with a sensor having a spectral sensitivity curve corrected to that of the average human eye. The SI (international metric standard) units for luminance are candelas per meter squared, but the English footlamberts are still used extensively in the United States. One footlambert = 3.4263 candelas/m². 6. Luminous flux per unit solid angle and per unit area measured normal to the direction of propagation of the flux.

luminance channel—In a color television system, any path intended to carry the luminance signal. The luminance channel may also carry other signals such as the color carrier, which may or may not be used.

luminance channel bandwidth—The bandwidth of the path intended to carry the luminance signal.

luminance contrast—The observed brightness of a light-emitting element compared to the brightness of the surround, an integral part of the device and inseparable from it.

luminance factor—Ratio of the luminance of the specimen to that of a perfect reflecting or transmitting diffuser identically illuminated.

luminance flicker—The flicker resulting from fluctuation of the luminance only.

luminance meter—A type of photometer calibrated in luminance units (candelas per square unit, or lamberts). In photography, an exposure meter contains a luminance meter to record the average luminance of a scene.

luminance primary—The one of three transmission primaries whose amount determines the luminance of a color.

luminance range—An objective measure of an object's brightness that is derived from the ratio of the luminances of its lightest and darkest sections.

luminance ratio—The ratio between the luminances (photometric brightness) of any two areas in the visual field.

luminance signal—Also called Y signal. 1. The signal in which the amplitude varies with the luminance values of a televised scene. It is part of the composite color signal and is made up of 0.30 red, 0.59 green, and 0.11 blue. The luminance signal is capable of producing a complete monochromatic picture. 2. That portion of the NTSC color television signal which contains the luminance or brightness information.

luminescence—1. The absorption of energy by matter, and its subsequent emission as light. If the light is emitted within 10^{-8} second after the energy is absorbed, the process is known as fluorescence. If the emission takes longer, the process is called phosphorescence. 2. The emission of light of certain wavelengths or limited regions of the spectrum in excess of that due to incandescence and the emissivity of the surface. This property is not exhibited by all materials. 3. Emission of light due to any other cause than high temperature (incandescence). 4. A general term that is applied to the production of light, either visible or infrared, by the direct conversion of some other form of energy. The general term is then subdivided to denote the particular energy conversion involved (i.e., thermoluminescence, cathodoluminescence, photoluminescence, and electroluminescence). Luminescence includes both fluorescence and phosphorescence. Not to be confused with luminance (brightness).

luminescence threshold—Also called threshold of luminescence. The lowest radiation frequency that will excite a luminescent material.

luminescent—Any material that will give off light but not heat when energized by an external source such as a stream of electrons or radiant energy.

luminescent screen—A screen that becomes luminous in those spots excited by an electron beam. The screen of a cathode-ray tube is the best-known example.

luminosity—Ratio of luminous flux to the corresponding radiant flux at a particular wavelength. It is expressed in lumens per watt.

luminosity coefficients—The constant multipliers for the respective tristimulus values of any color. The sum of three products is the luminance of the color.

luminosity curve—A distribution curve showing luminous flux per element of wavelength as a function of wavelength.

luminosity factor—Abbreviated K. For radiation of a particular wavelength, the ratio of the luminous flux at that wavelength to the corresponding radiant flux. It is expressed in lumens per watt.

luminous—1. An adjective used to indicate the production of light, e.g., "luminous source," to distinguish from electrical sources, etc. It is sometimes used before "intensity" or "flux." 2. Pertaining to electromagnetic radiation as perceived by the eye.

luminous efficiency—The ratio of luminous flux to radiant flux. It is usually expressed in lumens per watt of radiant flux and should not be confused with the term

efficiency when applied to a practical source of light. The latter is based on the power supplied to the source—not the radiant flux from the source. For energy radiated at a single wavelength, luminous efficiency is synonymous with luminosity.

luminous emittance—The luminous flux emitted per unit area of the source; normal units of measurement are the lumen/cm² and the lumen/ft².

luminous energy—A measure of the time-integrated amount of flux. It has units of lumenseconds and could be used to describe such things as the radiant energy that the eye would receive from a photographic flash.

luminous flux—Also called light flux. 1. Time rate of flow of light (the total visible energy produced by a source per unit time). Usually measured in lumens. 2. Radiant power weighted at each wavelength in accordance with the ability of the eye to perceive it. 3. Radiant flux of wavelength within the band of visible light. 4. The radiant power of visible light modified by the eye response. It is the measure of the flow of visible light energy past any given point in space in a given period, and is defined as the amount of flux radiated by a source of 1 candela into a solid angle of 1 steradian.

luminous flux density (illumination)—Radiation flux density of wavelength within the band of visible light. Measured in lumens per square foot or footcandles. At the wavelength of peak response of the human eye, 0.555 μ m, 1 watt of radiative power is equivalent to 680 lumens.

luminous flux intensity—Luminous flux per unit solid angle (steradian).

luminous intensity—The ratio of luminous flux emitted by a source to the solid angle in which the flux is emitted. It is normally measured in terms of the lumen per steradian, which is the same as 1 candela.

luminous sensitivity—1. In a phototube, the output current divided by the incident luminous flux at a constant electrode voltage. (The term "output current" here does not include the dark current.) 2. The sensitivity of an object to light from a tungsten-filament lamp operating at a color temperature of 2870 K. This definition is permissible, since luminous sensitivity is not an absolute characteristic but depends on the spectral distribution of the incident flux.

luminous transmittance—The ratio of the luminous flux transmitted by an object to the incident luminous flux.

lumped—Concentrated in single, discrete elements rather than being distributed throughout a system.

lumped constant—1. The single quantity of a circuit property that is electrically equivalent to the total of that property distributed in a coil or circuit. 2. A resistance, inductance, or capacitance that is connected at a point, rather than being distributed uniformly throughout the circuit.

lumped-constant elements—Distinct electrical units smaller than a wavelength. They are calibrated and used, in conjunction with other electrical/electronic equipment, for controlling voltage and current.

lumped-constant oscillator—A microwave power-generation circuit that is realized by using discrete circuit elements such as inductors and capacitors.

lumped-constant tuned heterodyne-frequency meter—A device for measuring frequency. Its operation depends on the use of a tuned electrical circuit consisting of lumped inductance and capacitance.

lumped impedance—Impedance concentrated in a component, as distinguished from impedance due to stray or distributed effects.

lumped inductance—Inductance concentrated in a component, as opposed to stray or distributed inductance.

lumped loading—Inserting uniformly spaced inductance coils along the line, since continuous loading is impractical.

lumped parameter—Any circuit parameter which—for purposes of analysis—can be considered to represent a single inductance, capacitance, resistance, etc., throughout the frequency range of interest.

Luneberg lens—A type of lens used to focus radiated UHF electromagnetic energy to increase the gain of an antenna.

lux—Letter symbol: lx. 1. A practical unit of illumination in the metric system. It is equivalent to the metercandle and is the illumination on a 1 square-meter

area on which there is a uniformly distributed flux of 1 lumen. 2. International system (SI) unit of illumination in which the meter is the unit of length. One lux equals 1 lumen per square meter.

Luxemburg effect—A nonlinear effect in the ionosphere. As a result, the modulation on a strong carrier wave will be transferred to another carrier passing through the same region.

luxmeter—1. A type of illumination photometer employing a variable aperture and the contrast principle. 2. An illuminometer designed to measure illumination in terms of lux.

LVCD—Abbreviation for least voltage coincidence detection.

lx—Letter symbol for lux.

M

m—Letter symbol for the prefix milli-.

M—1. Symbol for mutual inductance. 2. Letter symbol for the prefix mega-, or meg-, meaning one million.

mA—Letter symbol for milliampere.

MA—Letter symbol for megampere.

MAC-B—An acronym for mixed analog component signals, system B. It refers to placing TV sound into the horizontal line-blanking period and then separating the color and luminance for periods of 20 to 40 microseconds each during horizontal scan. In the process, luminance and chroma are compressed during transmission and expanded during reception, enlarging their bandwidths considerably. Transmitted via satellite as FM, this system provides considerably better TV definition and resolution. Its present parameters are within the existing NTSC format.

mach—Unit of speed measurement equal to speed of sound. Sound travels 759 mph (1221 km/hr) at sea level; it decreases about 2 percent for every thousand feet of altitude.

machine—A term that is often used as a synonym for computer, workstation, or host.

machine-available time—In a computer, power-on time less maintenance time.

machine code—1. Code that is acceptable to the computing device on which the software is to be executed without further modification. 2. Commands for a computer or microprocessor system, often written in binary or hexadecimal format. Machine code is often referred to as machine language or object code. *See also* machine language. 3. In process planning, an alphanumeric code that identifies important machine-tool characteristics such as capacity, size, function, or capability. This number code can also be used in sorting routines to find similar machine types.

machine cycle—1. The shortest complete process or action that is repeated in order. The minimum length of time in which the foregoing can be performed. 2. The basic CPU cycle. In one machine cycle an address may be sent to memory and one word (data or instruction) read or written, or in one machine cycle a fetched instruction can be executed.

machine error—A deviation from the correct result in computer-processed data as a result of equipment failure.

machine hardware—Circuits contained in the five parts of the computer: input, output, control, storage, and arithmetic sections; any other circuit is offline.

machine independent—1. Pertaining to procedures or programs created without regard to the actual devices with which they will be used. 2. A term used to indicate that a program is developed in terms of the problem rather than in terms of the characteristics of the computer system.

machine instruction—An instruction that can be recognized and executed by a machine.

machine language—Also called object code, object language, or computer code. 1. A set of symbols, characters, or signs and the rules for combining them to convey instructions or data to a computer. 2. Programming language form directly executable by a computer. This language is nearly always expressed in numeric form, usually binary, octal, or hexadecimal. 3. A series of bits written as such for instruction of computers. The first level of computer language. *See* assembly language (second level); compiler language (third level). 4. Sets of numeric instructions that control the functioning of a computer. These numeric instructions execute the logic functions of the computer's logic circuits. For example, the instructions 010110 might tell the computer to clear the A register. To overcome the problems inherent in working with long strings of numbers, computer programs are more often written in assembly language.

machine learning—The ability of equipment to modify performance based on past experience stored in memory. Related to artificial intelligence.

machine ringing—Telephone ringing that is started either mechanically or by an operator and that continues automatically until the call is either answered or abandoned.

machine run—In a computer, the performance of one or more machine routines that are linked to form one operating unit.

machine sensible—Information in a form such that it can be read by a specific machine.

machine thermal relay—A device that functions when the temperature of an ac machine armature, or of the armature or other load-carrying winding or element of a dc machine, or converter, power rectifier, or power transformer (including a power-rectifier transformer), exceeds a predetermined value.

machine vision—The ability of an automated system to perform certain visual tasks normally associated with human vision, including sensing image formation, image analysis, and image interpretation or decision making.

machine word—*See* computer word.

macro—1. A single pseudoinstruction that, when encountered by software or hardware, invokes the execution of a number of real instructions. 2. A stored set of keystrokes. They allow for quick execution of often repeated tasks, such as setting margins or tabs that are uniform to a particular business. 3. A symbol that the assembler expands into one or more machine language instructions, relieving the programmer of having to write out frequently occurring instruction sequences. 4. An instruction in an assembly language that is implemented in machine language by more than one machine language instruction.

macroassembler—1. An assembler that facilitates definition of macros for frequently used code segments. Macroassemblers simplify program coding; however, unlike subroutine calls, they generate in-line code for each reference. 2. A computer assembly program that translates alphanumeric language into machine language.

macrocode—1. A coding system that assembles groups of computer instructions into single code words and which therefore requires interpretation or translation so that an automatic computer can follow it. 2. An instruction in a source language that is equivalent to a specified sequence of machine instructions.

macrocommand—A computer program entity formed by a string of standard, but related, commands that are put into effect by means of a single macrocommand. Any group of frequently used commands can be combined into a macrocommand. The many become one.

macroelement—An ordered set of two or more elements used as one data element with one data use identifier. For example, the macroelement date could be the ordered set of the data elements year, month, or day.

macroinstruction—1. In a computer, a source-language instruction that is equivalent to a specified sequence of machine instructions. 2. Either a conventional computer instruction (e.g., ADD MEMORY TO REGISTER, INCREMENT, SKIP) or device controller command (e.g., seek, read).

macroprogram—A computer program in the form of a sequence of instructions written in a source language.

macroprogramming—In a computer, the writing of machine-procedure statements in terms of macrocode instructions.

macros—Computers that have a throughput of 2 gigabits (2×10^9 bits) per second and a memory size of 2 megabytes.

macroscopic—Large enough to be observed by the unaided eye.

macrosonics—The utilization of high-amplitude sound waves for performing functions such as cleaning, drilling, emulsification, etc.

madistor—A semiconductor device that makes use of the effects of a magnetic field on a plasma current. The strength of a magnetic field determines the conductivity of the madistor material. A small change in the magnetic field produces a larger change in the madistor current.

MADT—Abbreviation for microalloy diffused-base transistor.

magamp—Abbreviation for magnetic amplifier.

magic eye—*See* electron-ray tube.

magic tee—*See* hybrid junction, 1.

magnaflex—A magnetic method of determining surface and subsurface defects in metals.

magnal base—An 11-pin base used on cathode-ray tubes.

magnal socket—An 11-pin socket used with cathode-ray tubes.

magnesium—An alkaline metal whose compounds are sometimes used for cathodes.

magnesium anode—A bar of magnesium, buried in the earth, connected to an underground cable to prevent cable corrosion due to electrolysis.

magnesium cell—A primary cell whose negative electrode is made of magnesium or one of its alloys.

magnesium-copper sulfide rectifier—A dry disc rectifier consisting of magnesium in contact with copper sulfide.

magnesium-silver chloride cell—A reserve primary cell that becomes activated when water is added.

Magnesyn—Trade name for a device made by Bendix Aviation Corp. It is a portion of a repeater unit

macroassembler — magnetic-armature speaker

consisting of a two-pole permanent-magnet rotor within a three-phase, two-pole, delta-connected stator. The rotor carries the indicating pointer and is free to rotate in any direction.

magnet—A body that has the property of attracting or repelling magnetic materials. In its natural form it is called a lodestone. It may also be produced by permanently magnetizing a piece of iron or steel. A temporary magnet—called an electromagnet—is produced by passing a current through a coil surrounding a piece of iron or steel; the magnetism persists only while current is flowing. When suspended freely, a magnet will turn and align its poles with the north and south magnetic poles of the earth. *See also* electromagnet; permanent magnet.

magnet brake—A friction brake controlled electromagnetically.

magnetic—Pertaining to magnetism.

magnetic aging—The normal change in the metallurgical change in the material. The term also applies when the metallurgical changes are accelerated by an increase or decrease in temperature. When used in reference to core loss, this term, unless otherwise modified, implies an increase in loss. When used in reference to permeability or remanence, the term, in a positive sense, indicates a decrease in these quantities.

magnetic air gap—The air space, or nonmagnetic portion, of a magnetic circuit.

magnetic alarm system—An alarm system that will initiate an alarm when it detects changes in the local magnetic field. The changes could be caused by motion of ferrous objects, such as guns or tools, near the magnetic sensor.

magnetically damped—A form of damping achieved by moving a metal vane through a magnetic field. This motion induces currents in the vane that set up magnetic fields opposing those of the stationary magnets, thus tending to bring the pointer to rest. This type of damping is found in many quality moving-iron and dynamometer-type instruments.

magnetically hard—A rather loose term not always synonymous with “hard” metallurgically. Used to designate a permanent-type magnetic material, i.e., an alloy having a high coercive force and residual induction.

magnetically isotropic—A material having the same magnetic characteristics along any axis or orientation. Could be considered the antonym of anisotropic.

magnetically polarized—The magnetic orientation of molecules in a piece of iron or other magnetizable material placed in a magnetic field, whereby the tiny internal magnets tend to line up with magnetic lines of force.

magnetically soft—A rather loose term not always synonymous with “soft” metallurgically. Used to designate a ferromagnetic material having a low coercive force.

magnetic amplifier—Often called magamp. 1. A device in which one or more saturable reactors are used, either alone or with other circuit elements, to obtain power gain. 2. A device in which a control signal applied to a system of saturable reactors modulates the flow of an alternating current in a power circuit.

magnetic analysis—The separation of a stream of electrified particles by a magnetic field in accordance with their mass, charge, or speed. This is the principle of the mass spectrograph.

magnetic anisotropy—The dependence of the magnetic properties of some materials on direction.

magnetic-armature speaker—Also called a magnetic-armature loudspeaker or magnetic speaker. A speaker comprising a ferromagnetic armature actuated by magnetic attraction.

Magnetic amplifiers.

magnetic azimuth — Azimuth measured from magnetic north.

magnetic bearing — The position in which an object is pointing with respect to the earth's magnetic north pole. It is expressed in degrees clockwise from that pole.

magnetic bias — A steady magnetic field applied to the magnetic circuit of a relay.

magnetic biasing — The superimposing of another magnetic field on the signal magnetic field of a tape while a magnetic recording is being made.

magnetic bipolar sensor — Solid-state Hall-effect sensor that has a plus (south pole) maximum operate point and a minus (north pole) minimum release point. Because the operate and release points can be both positive or both negative, latching cannot be guaranteed. The sensor usually used in ring magnet applications. *Compare* latching sensor.

magnetic blowout — A magnet for establishing a field where an electrical circuit is broken. The field lengthens the arc and thus helps to extinguish it.

magnetic blowout switch — A switch that contains a small permanent magnet that provides a means of switching high dc loads. The magnet deflects the arc to quench it.

magnetic braking — Application of the brakes by magnetic force. The current for exciting the electromagnets is derived either from the traction motors acting as generators or from an independent source.

magnetic bremsstrahlung — *See* synchrotron radiation.

magnetic brush — In the electrostatic process, a device used to transport toner particles to the surface of the photoconductor. A brush is mounted on a roller mechanism. As it turns, its magnetic pull attracts toner particles and carries them to the drum surface, where they are deposited. *See* electrostatic process.

magnetic brush development — A type of development in which the material that forms the image is carried to the field of the electrostatic image by ferromagnetic particles that act as carriers under the influence of a magnetic field.

magnetic bubble — 1. A cylindrical magnetic domain with a polarization opposite to that of the thin magnetic film in which it is embedded. Domains form in a crystalline magnetic material in such a way as to minimize the total magnetic energy of the crystal. 2. Small, cylindrical domain formed in single-crystal thin films of synthetic ferrites or garnets, or in thin, amorphous magnetic-metal films when a stationary external magnetic bias field is applied perpendicularly to the plane of the films. These domains are mobile in the presence of a magnetic field gradient, and their direction of movement can be controlled by special structures deposited on top of the film and by a moving magnetic field. As the bias field increases in strength toward its optimum value, randomly distributed serpentine domains in the film layer shrink until they form the cylindrical domains, or bubbles. Once the bubbles are formed, they can be moved along a path defined by a deposited layer of metal on the surface of the magnetic film. The presence of a bubble corresponds to a logical 1 and absence to a logical 0.

magnetic bubble film — An amorphous film in which cylindrical bubbles of reverse magnetization can be formed to follow circuit paths usually made by depositing magnetic metal strips on the film surface. They are used in magneto-optic storage and processing of computer data.

magnetic bubble memory — A type of memory made of cylindrically shaped magnetic domains, called magnetic bubbles, formed in a thin-film layer of single-crystal synthetic ferrite or garnet when a magnetic field is applied perpendicular to the film's surface. A separate, rotating, magnetic field moves the bubbles through the film in shift register fashion. The presence of a bubble represents a digital 1 and the absence of a bubble, a digital 0. The basic bubble memory consists of a bubble memory chip, magnetic field coils that produce the rotating magnetic field, and two permanent magnets that maintain the magnetic bubble domains and nonvolatility.

magnetic bubble memory controller — A high-level interface between a microprocessor and a bubble memory. The controller performs parallel-to-serial conversion from the microprocessor to the bubble memory, and serial-to-parallel conversion from the bubble memory to the microprocessor. The controller's primary functions are to stop and start bubble movement, maintain page position, and raise or lower flags for such bubble memory functions as generate, swap, block replicate, and redundancy replicate. Control signals from the bubble memory controller are sent to the function timing generator—a monolithic IC that provides the precise timing signals necessary to operate the function driver, coil driver, and sense amplifier during each field cycle. (Obsolete technology).

magnetic card — A card on which data can be stored by selective magnetization of portions of a flat magnetic strip such as that found on credit cards.

magnetic card reader — A device that can retrieve information stored in a magnetic strip.

magnetic cartridge — *See* variable-reluctance pickup.

magnetic character — A character imprinted with ink having magnetic properties. These characters are unique in that they can be read directly by both humans and machines.

magnetic circuit — The path of the flux as it travels from the north pole, through the circuit components, and back to the north pole. In a generator, the magnetic-circuit components include the field yoke, field pole pieces, air gap, and armature core. The magnetic circuit may be compared to an electrical circuit, with magnetomotive force corresponding to voltage, flux lines to current, and reluctance to resistance.

magnetic circuit breaker—1. A circuit breaker that depends on the response of an electromagnetic coil for operation. 2. In their simplest form, a latching relay with normally closed contacts. When enough current flows through the coil, the armature is pulled in, transferring the contacts, which latch in their open position. In a magnetic breaker, the coil is wound so that the field generated by the rated current is not quite strong enough to pull in the armature. Any increase in current above the rated level increases the field strength enough to transfer the contacts and open the circuit.

magnetic coated disc—A magnetic disc-recording medium consisting of a coat of magnetizable material over a nonmagnetic base.

magnetic coating thickness—See coating thickness.

magnetic coil—The winding of an electromagnet.

magnetic compass—A device for indicating direction. It consists of a magnetic needle that pivots freely and points toward the earth's north magnetic pole.

magnetic conduction current—The rate of flow of magnetism through a magnetized body.

magnetic contactor—A contactor actuated electromagnetically.

magnetic controller—An electric controller that contains devices operated by means of electromagnets.

magnetic-convergence principle—The obtaining of beam convergence through the use of a magnetic field.

magnetic core—1. A configuration of magnetic material that is, or is intended to be, placed in a rigid special relationship to current-carrying conductors, and the magnetic properties of which are essential to its use. For example, it may be used to concentrate an induced magnetic field, as in a transformer, induction coil, or armature; to retain a magnetic polarization for the purpose of storing data; or for its nonlinear properties, as in a logic element. It may be made of such material as iron, iron oxide, or ferrite in such shapes as wires, tapes, toroids, or thin film. 2. The ferrous material in the center of an electromagnet.

magnetic core storage—A type of computer storage that employs a core of magnetic material surrounded by a coil of wire. The core can be magnetized to represent a binary 1 or 0. (Obsolete technology).

magnetic course—A course in which the reference line is magnetic north.

magnetic cutter—A cutter in which the mechanical displacement of the recording stylus is produced by the action of magnetic fields.

magnetic cycle—The sequence of changes in the magnetization of an object corresponding to one cycle of the alternating current producing the magnetization.

magnetic damping—1. The damping of a mechanical motion by means of the reaction between a magnetic field and the current generated in a conductor moving through that field. The resistance of this conductor converts excess kinetic energy to heat. 2. The slowing down of mechanical motion by the reaction between two magnetic fields. A common example is the metal disc that rotates between the poles of a permanent magnet in a watt-hour meter.

magnetic deflection—The moving of the electron beam by means of a magnetic field produced by a coil around the neck of the cathode-ray tube. Linear motion is produced by a sawtooth current through the coil.

magnetic delay line—A computer delay line in which magnetic energy is propagated, consisting in essence of a metallic medium along which the velocity of propagation of magnetic energy is small when compared with the speed of light. The storage of information,

Magnetic deflection.

which is usually in a binary form, is accomplished by recirculation of wave patterns.

magnetic density—The number of lines of magnetic force passing through a magnet or magnetic field per unit area of cross section.

magnetic detecting device—A device for detecting cracks in iron or steel. This is done by introducing magnetic particles, which are attracted to the opposing magnetic poles created at the break.

magnetic device—Any device actuated electromagnetically.

magnetic digital versatile disc—Abbreviated M-DVD.

magnetic diode—A magnetism-sensitive semiconductor device that (like indium-antimony devices) has an internal resistance that varies as a function of an external magnetic field. Electrical signals may be obtained through alternation of the magnetic field, and, hence, nonelectrical quantities can be converted into electrical quantities.

magnetic dip—Also called magnetic inclination. The angle of the magnetic field of the earth with the horizontal at a particular location.

magnetic dipole—A pair of equal-strength north and south magnetic poles spaced close together, and so small that its directive properties are independent of its size and shape. It is the magnetic equivalent of an electrical dipole.

magnetic dipole antenna—A loop antenna that radiates an electromagnetic wave when electric current circulates in the loop.

magnetic direction indicator—Abbreviated MDI. An instrument that provides a compass indication, which it obtains electrically from a remote gyro-stabilized magnetic compass (or its equivalent).

magnetic disc—Also disk. 1. A flat circular plate with a magnetic surface on which data can be stored by selective magnetization of portions of the flat surface. 2. A metal or plastic (floppy) disk looking something like a phonograph record whose surface can store data in the form of magnetized spots.

magnetic disk storage—1. A device or system in which information is stored in the form of magnetic spots arranged on the surfaces of magnetically coated disks to represent binary data. 2. A storage device or system made up of magnetically coated metal disks.

magnetic disk unit—A device used to read and write data on thin magnetic disks, the surfaces of which have been coated with a magnetizable material.

magnetic displacement—Magnetic flux density or magnetic induction.

magnetic domain—A volume within a magnetic material where the direction of magnetization is everywhere the same.

magnetic drum—1. A storage device consisting of a rapidly rotating cylinder whose surface can be easily magnetized and that will retain the magnetization. Information is stored in the form of magnetized spots (or no spots) on the drum surface. 2. A right circular cylinder with a magnetic surface on which information can be stored by selective magnetization of parts of the curved surface.

magnetic-drum receiving equipment—Radar developed for detection of targets beyond line of sight using ionospheric reflection and very low power. To distinguish radar signals from ground noise, a noise-free standard system is employed whereby the amplitude and characteristics are reproduced and preserved for comparison with returned signals. Fluctuations in the amplitude of the returned signals indicate the position and velocity of the target accurately to within 10 miles (16 km).

magnetic drum storage—A device or system that uses a magnetic drum to store information.

magnetic drum unit—A device used to read and write data on a cylinder, the surface of which is covered with a magnetizable material.

magnetic electron multiplier—One type of electron multiplier in which the paths of the emitted secondary electrons are controlled by an externally applied magnetic field.

magnetic-energy product curve—The graphical representation of the energy per unit volume produced by a magnet. It is the product of the flux density and demagnetizing field as shown on the normal demagnetization curve. The maximum of this product as shown on such a curve is known as $B_d H_d$ max.

magnetic field—An area where magnetic forces can be detected around a permanent magnet, natural magnet, or electromagnet.

Magnetic field.

magnetic field strength—See magnetizing force.

magnetic figures—A pattern showing the distribution of a magnetic field. It is made by sprinkling iron filings on a nonmagnetic surface in the field.

magnetic flip-flop—A bistable amplifier using one or more magnetic amplifiers. The two stable output levels are determined by appropriate changes in the control voltage or current.

magnetic fluid—A fluid having three components: a carrier fluid, magnetite particles suspended by Brownian motion, and a stabilizer to prevent agglomeration of these fine particles. It is characterized by its viscosity and saturation magnetization value.

magnetic flux—1. The magnetic induction in a material. An electromotive force will be induced in a conductor placed in a magnetic field whenever the magnitude of the flux changes. 2. A condition in a medium produced by a magnetomotive force such that,

when altered in magnitude, a voltage is induced in an electric circuit linked with the flux. The cgs unit of magnetic flux is called the maxwell.

magnetic flux density—See magnetic induction.

magnetic focusing—The focusing of an electron beam by the action of a magnetic field.

magnetic freezing—In a relay, sticking of the armature to the core due to residual magnetism.

magnetic fusion—A fusion process that occurs when a burning plasma is confined by externally imposed magnetic fields.

magnetic gap—The nonmagnetic part of a magnetic circuit.

magnetic gate—A gate circuit used in a magnetic amplifier.

magnetic head—In magnetic recording, a transducer that converts electric variations into magnetic variations for storage on magnetic media or for reconverting such stored energy into electric energy. Stored energy can also be erased by this method.

magnetic heading—The heading of an aircraft with reference to magnetic north.

magnetic hysteresis—In a magnetic material, the property by virtue of which the magnetic induction for a given magnetizing force depends on the previous conditions of magnetization.

magnetic hysteresis loop—A closed curve that shows the induction of magnetization in a magnetic substance as a function of the magnetization force for a complete cycle of the magnetization force.

magnetic hysteresis loss—The power expended in a magnetic material as a result of magnetic hysteresis when the magnetic induction is cyclic.

magnetic inclination—See magnetic dip.

magnetic induction—Also called magnetic flux density (B). The flux per unit area (A) perpendicular to the direction of the flux (ϕ). The cgs unit of induction is called the gauss (plural, gaussses) and is defined by the equation $B = d\phi/dA$.

magnetic ink—Visible ink containing magnetic particles. When printed on a document (e.g., a bank check), the ink can be read by a magnetic character sensor and also by humans.

magnetic-ink character recognition—Abbreviated MICR. 1. Machine recognition of characters printed with magnetic ink. (Contrast with OCR.) 2. A system of coding in which numeric and special characters are printed with magnetizable ink. 3. A mechanized method of data collection involving the electronic reading of data that has been printed in magnetic ink. Most checks have the bank transit number imprinted in magnetic ink at the lower-left part of the check.

magnetic instability—The property of a magnetic material that leads to variations in the residual flux density of a recording tape with time, mechanical flexing, or changes in temperature.

magnetic integrated circuit—An integrated component that utilizes one or more magnetic elements inseparably associated to perform all or at least a major portion of its intended function.

magnetic-latch relay—See polarized double-biased relay.

magnetic leakage—Passage of magnetic flux outside the path along which it can do useful work.

magnetic lens—1. An apparatus that uses a nonuniform magnetic field to focus beams of rapidly moving electrons or ions in a cathode-ray or other tube. 2. An arranged series of coils, magnets, or electromagnets disposed in such a way that the resulting magnetic fields are used to focus beams of rapidly moving electrons or ions.

magnetic line of force—In a magnetic field, an imaginary line that has the direction of the magnetic flux at every point.

magnetic materials—Materials that show magnetic properties. Ferromagnetic materials are more strongly magnetic than paramagnetic materials.

magnetic medium—Any data-storage medium and related technology, including disks, diskettes, and tapes, in which different patterns of magnetization are used to represent bit values.

magnetic memory—A computer memory (or any portion) in which information is stored in the form of magnetism.

magnetic memory disk—A mass-memory storage element that is a large and rigid rotating circular plate coated with magnetic material, such as iron oxide. Data is written (stored) and read (retrieved) by fixed or movable read/write heads positioned over data tracks on the surface of the disk. Addressable portions are selectable for read and write operations.

magnetic memory plate—A magnetic memory that consists of a ferrite plate containing a grid of small holes through which the read-in and read-out wires are threaded. Printed wiring applied directly to the plate may replace conventionally threaded wires, making possible mass production of plates with a high storage capacity.

magnetic microphone—*See* variable-reluctance microphone.

magnetic mine—An underwater mine that detonates when near the steel hull of a ship. This is accomplished by relays that redistribute the magnetic field in the mine when it is near the ship.

magnetic modulator—Also called a magnetor. A modulator employing a magnetic amplifier as the modulating element.

magnetic moment—Ratio of the maximum torque exerted on a magnet to the magnetizing force of the field in which the magnet is situated.

magnetic needle—The magnetized needle used in a compass. When freely suspended, it will point to the earth's magnetic north and south poles.

magnetic north—The direction indicated by the north-seeking end of the needle in a magnetic compass.

magnetic phase modulator—A ferrite-core delay line in which the delay is varied by an external magnetic field.

magnetic pickup—*See* variable-reluctance pickup.

magnetic-plated wire—A wire with a nonmagnetic core and a plated surface of ferromagnetic material.

magnetic poles—Those portions of a magnet toward which the lines of flux converge. All magnets have two poles, called north and south, or north-seeking and south-seeking, poles.

Magnetic poles.

magnetic line of force — magnetic saturation

magnetic pole strength—The magnetic moment of a magnetized body divided by the distance between the poles.

magnetic potential difference—The line integral of magnetizing force between two points in a magnetic field.

magnetic-powder-coated tape—Also called coated tape. A tape consisting of a coating of uniformly dispersed powdered ferromagnetic material on a nonmagnetic base.

magnetic printing—Also called magnetic transfer or crosstalk. The permanent transfer of a recorded signal from a section of one magnetic recording medium to another section of the same or a different medium when they are brought near each other.

magnetic probe—A loop-type conductor for detecting the presence of static, audio, or rf magnetic fields.

magnetic radio bearing—*See* radio bearing.

magnetic recorder—Equipment incorporating an electromagnetic transducer and a means for moving a magnetic recording medium past the transducer. Electric signals are recorded in the medium as magnetic variations. *See also* magnetic recording.

magnetic recording—Recording audio frequencies by magnetizing areas of a tape or wire. The magnetized tape or wire is played back by passing it through a reproducing head. Here the magnetized areas are reconverted into electrical energy, which headphones or speakers then change back into sound.

magnetic recording head—In magnetic recording, a magnetic head that transforms electric variations into magnetic variations for storage on a magnetic medium such as tape or disks.

magnetic recording medium—A wire, tape, cylinder, disk, or other magnetizable material that retains the magnetic variations imparted to it during magnetic recording.

magnetic reproducer—Equipment that picks up the magnetic variations on magnetic recording media and converts them into electrical variations.

magnetic reproducing head—In magnetic recording, the head that converts the magnetic variations into electric variations.

magnetic rod—A square-loop switching and storage element for digital systems. It consists of a silver-coated glass rod upon which a thin layer of iron and nickel is deposited. Conductors are wound around the rod for the drive, sense, enable, and inhibit currents.

Magnetic rod.

magnetics—The branch of science concerned with the laws of magnetic phenomena.

magnetic saturation—1. In an iron core, the point at which application of a further increase in magnetizing force will produce little or no increase in the magnetic lines of force. 2. The condition under which all elementary moments have become oriented in one direction.

magnetic separator—An apparatus for separating powdered magnetic ores from nonmagnetic ores, or iron filings and other small iron objects from nonmagnetic materials. An electromagnet is employed, which deflects the magnetic materials from the path taken by the nonmagnetic materials.

magnetic shield—A sheet or core of iron enclosing instruments of radio parts to protect them from stray magnetic fields. The shield provides a convenient path for the magnetic lines of force and thus diverts them from the component being protected.

magnetic shielding—Iron, steel, nickel, mu-metal, or other magnetic material used to exclude unwanted electromagnetic fields from circuitry, transformers, or conductors.

magnetic shift register—A register in which magnetic cores are used as binary storage elements. By means of pulses, the pattern of binary digital information can be shifted one position to the left or right in the register.

magnetic shunt—A piece of iron used during instrument calibration to divert a portion of the magnetic lines of force passing through an air gap in the instrument.

magnetic sound—Sound recording in which magnetic impulses are stored in a ferric emulsion bonded to plastic or film.

magnetic speaker—A speaker in which acoustic waves are produced by mechanical forces resulting from magnetic reaction.

magnetic starter—A starter actuated electromagnetically.

magnetic storage—Any storage system such as tape, diskette, or other form of magnetic media that makes use of the magnetic properties of materials to store information.

magnetic storm—A disturbance in the earth's magnetic field. It is associated with abnormal solar activity and is capable of disrupting both radio and wire transmission.

magnetic strain gage—Also spelled gauge. An instrument for measuring strain in rails or other structural members that bend only microscopically under a normal load. It does this by determining the change in reluctance of a magnetic circuit having a movable armature.

magnetic strip—Sheet or foil aluminum (either bare or insulated) used as a conductor in electric windings. Copper is also used sometimes.

magnetic susceptibility—Ratio of the intensity of magnetization to the corresponding value of the magnetizing force.

magnetic switch—A switch that consists of two separate units: a magnetically actuated switch and a magnet. The switch is usually mounted in a fixed position (door jamb or window frame) opposing the magnet, which is fastened to a hinged or sliding door, window, etc. When the movable section is opened, the magnet moves with it, actuating the switch.

magnetic tape—1. The recording medium used in tape recorders. A paper or plastic tape on which a magnetic emulsion (usually ferric oxide) has been deposited. The most common width for home recorders is $\frac{1}{4}$ inch (6.35 mm). Some tapes are made of a magnetic material and hence need no magnetic-emulsion coating. 2. Tape made of plastic and coated with magnetic material; used to store information.

magnetic tape core—A toroidal core made by winding a strip of thin magnetic-core material around a form. A toroidal winder is then used to wind coils around the core.

magnetic tape reader—A computer device capable of converting the information recorded on magnetic tape into corresponding electric pulses.

magnetic tape storage—A storage system based on the use of magnetic spots (bits) on metal or coated-plastic tape; the spots are arranged so that the desired code is read out as the tape travels past the read-write head.

magnetic tape unit—A device used to read and write data in the form of magnetic spots on reels of tape coated with a magnetizable material.

magnetic test coil—Also called search or exploring coil. 1. A coil that is connected to a suitable device to measure a change in the magnetic flux linked with it. The flux linkage may be changed by either moving the coil or varying the magnitude of the flux. 2. The coil used with a ballistic galvanometer or flux meter to measure the magnetic flux.

magnetic thin film—A layer of magnetic material, usually less than 10,000 angstroms thick. In electronic computers, magnetic thin films may be used for logic or storage elements.

magnetic transducer—*See* variable-reluctance transducer.

magnetic transfer—*See* magnetic printing.

magnetic transition temperature—Also called the Curie point. In a ferromagnetic material, the point at which its transition to paramagnetic seems to be complete as its temperature is raised.

magnetic tubes of flux—Region in space whose sides are everywhere tangent to the magnetic induction and whose ends may meet to form closed rings.

magnetic units—Ampere-turn, gauss, gilbert, line of force, maxwell, oersted, and unit magnetic pole are examples of magnetic units—i.e., those used in measuring magnetic quantities.

magnetic-vane meter—Also called a moving-vane meter. A meter for measuring alternating current. It contains a metal vane that pivots inside a coil. Alternating current flows through the coil and sets up magnetic forces that rotate the vane and attached pointer in proportion to the value of the current.

magnetic variometer—An instrument for measuring the difference in a magnetic field with respect to space or time.

magnetic vector—A term denoting the amplitude and direction of the magnetic field associated with an electromagnetic wave.

magnetism—A property possessed by certain materials by which these materials can exert mechanical force on neighboring masses of magnetic materials and can cause voltages to be induced in conducting bodies moving relative to the magnetized bodies.

magnetite—A mineral that exists in a magnetized condition in its natural state. It consists chiefly of a magnetic oxide of iron.

magnetization curve—A curve plotted on a graph to show successive states during magnetization of a ferromagnetic material. A normal magnetization curve is a portion of a symmetrical hysteresis loop. A virgin magnetization curve shows what happens to the material the first time it is magnetized.

magnetization intensity—At any point in a magnetized body, the ratio between the magnetic moment of the element of volume surrounding the point and an infinitesimal volume.

magnetize—To make magnetic.

magnetizing current—Also called exciting current. The current through the field windings of a generator.

magnetizing field—The magnetomotive force per unit length at any given point in the magnetic circuit. In

the cgs system the unit is the oersted. It is defined by the quotient

$$\frac{\text{magnetomotive force in gilberts}}{\text{length in centimeters}}$$

magnet keeper—A bar of iron or steel placed across the poles of a horseshoe magnet when the magnet is not in use. The keeper prevents the magnet from becoming demagnetized, by completing the magnetic circuit to keep the flux from leaking off.

Magnet keeper.

magnet meter—Also called a magnet tester. An instrument for measuring the magnetic flux produced by a permanent magnet. It usually comprises a torque-coil or moving-magnet magnetometer with a particular arrangement of pole pieces.

magneto—1. An ac generator for producing ringing signals. 2. An ac generator for producing the ignition voltage in some gasoline engines. 3. An engine-driven unit that generates high voltage to fire the spark plugs. It needs no outside source of power such as a battery.

magnetodiode—A high-sensitivity magnetosensitive semiconductor that operates on the principle of controlled lifetime of injected carriers by an external magnetic field.

magnetoelastic coupling—Energy transfer between elastic and spin-wave modes of propagation. The strength of the effect varies with the material used.

magnetoelastic energy—In a crystal, energy of interaction between elastic (or lattice) strains and applied magnetization. If a ferromagnetic crystal is placed in a magnetic field, or if a magnetic field is varied about the crystal, the lattice structure of the crystal is distorted (magnetostriction occurs) and changes the amount of potential energy in the lattice. The energy associated with this change is magnetoelastic.

magnetoelastic wave—A hybrid of spin and elastic waves.

magnetolectric generator—An electric generator with permanent-magnet field poles.

magnetolectric surface waves—Extensions of bulk magnetoelastic waves phenomena, which combine acoustic and spin wave properties. The spin waves, created by oscillations of the angle between adjacent atomic moments in a ferromagnetic solid, have high dispersive characteristics that depend on a dc magnetic field. A strain of a crystal lattice can affect the magnetic movements, resulting in a coupling between acoustic and spin waves. This coupling is most effective when wavelengths and frequencies of the two waves are comparable.

magnetolectric transducer—A transducer that measures the emf generated by the movement of a conductor relative to a magnetic field.

magnetofluid dynamics—*See* magnetohydrodynamics.

magnet keeper — magnetoresistance

magnetofluidmechanics—*See* magnetohydrodynamics.

magnetogas dynamics—*See* magnetohydrodynamics.

magnetograph—A magnetometer that provides a continuous record of the changes occurring in the earth's magnetic field.

magnetohydrodynamic power generation—Also called hydromagnetic power generation. The generation of electric current by the motion of an ionized gas.

Magnetohydrodynamic generator.

magnetohydrodynamics—The study and application of the effects of electric and magnetic fields on conducting fluids and superheated ionized gases.

magnetoionic—Pertaining to the combined effect of atmospheric ionization and the magnetic field of the earth on electromagnetic wave propagation.

magnetoionic duct—A duct along the geomagnetic lines of force that exhibits waveguide characteristics for radio-wave propagation between conjugate points on the earth's surface.

magnetoionic wave component—Either of the two elliptically polarized wave components into which a linearly polarized wave in the ionosphere is separated by the earth's magnetic field.

magnetometer—An instrument for measuring the intensity or direction (or both) of a magnetic field or of a component of a magnetic field in a particular direction.

magnetomotive force—The force by which a magnetic field is produced, either by a current flowing through a coil of wire or by the proximity of a magnetized body. The amount of magnetism produced in the first method is proportional to the current through the coil and the number of turns in it. The cgs unit of magnetomotive force is called the gilbert.

magneto-optical switch—A device used for digital modulation that consists of a magnetic film deposited on a substrate. A small digital voltage impressed on the film creates a magnetic field in the film that polarizes light passing through the film. The polarized light beam can then be sent through a polarizing filter that, depending on the direction of the light polarization, will either pass or block the light beam.

magnetoplasmadynamic generator—A device that generates an electric current by shooting an ionized gas (plasma) through a magnetic field.

magnetoresistance—The change in electrical conductivity of a material when a magnetic field is applied. This change is quite pronounced in materials with a high carrier mobility.

Magnetoresistor.

magnetoresistor—A semiconductor device in which the electrical resistance is a function of the applied magnetic field.

magnetosphere—A 900-mile thick belt in the upper atmosphere, composed primarily of helium gas.

magnetostatic field—A magnetic field that is neither moving nor changing direction. Such a field could be produced by a stationary magnetic pole or by a constant current flowing in a stationary conductor.

magnetostriction—That property of certain ferromagnetic metals, such as nickel, iron, cobalt, and manganese alloys, which causes them to shrink or expand when placed in a magnetic field. Conversely, if subjected to compression or tension, the magnetic reluctance changes, thus making it possible for a magnetostrictive wire or rod to vary a magnetic field in which it may be placed. This is true for lateral as well as longitudinal strains.

magnetostriction microphone—A microphone in which the deformation of a magnetostrictive material generates the required voltages.

magnetostriction oscillator—An oscillator in which the frequency is determined by the characteristics of the magnetostrictive element that inductively couples the plate circuit to the grid circuit.

magnetostriction speaker—A speaker in which the mechanical displacement is derived from the deformation of a magnetostrictive material.

magnetostriction transducer—A transducer comprising an element of magnetostrictive material inside a coil, and a force-summing member attached to one end of the element. Current flows through the coil, and the magnetic field around it expands and contracts the element to move the member back and forth.

Magnetostriction transducer.

magnetostrictive delay line—A delay line made of nickel or certain other materials that become shorter when placed in a magnetic field.

magnetostrictive filter—A filter network that uses the magnetostrictive phenomenon to form high-pass, low-pass, bandpass, or band-elimination filters. The impedance characteristic is the inverse of that of a crystal.

magnetostrictive oscillator—An oscillator in which a magnetostrictive element controls the frequency.

magnetostrictive relay—A relay that functions because of dimensional changes occurring in a magnetic material under the influence of a magnetic field.

magnetostrictive resonator—A ferromagnetic rod that can be excited magnetically so that it will resonate (vibrate) at one or more desired frequencies.

magnetostrictive transducer—Sensor using contraction or expansion of an iron or nickel rod due to a magnetic field. Magnetostrictive elements are used in magnetostriction oscillators.

magneto switchboard exchange—A manual telephone exchange arranged so that calling and clearing by the subscribers and operators are done by means of magnetolectric generators.

magneto telephone—A telephone equipped with a magneto (a hand-driven, two-pole, ringing-signal generator). Although obsolete for home and business telephones, it is still used in many field applications.

magnetron—An electric tube used to generate high power output in the UHF and SHF bands. The basis of its operation is the interaction of electrons with the electric field of a circuit element in crossed steady electric and magnetic fields to generate alternating-current power output.

Magnetron.

magnetron effect—In a thermionic vacuum tube, the reduced electron emission due to the magnetic field of the filament current.

magnetron oscillator—An electron tube in which electrons are accelerated by a radial electric field between the cathode and one or more anodes and by an axial magnetic field that provides a high-energy electron stream to excite the tank circuits.

magnetron pulling—A shift in the frequency of a magnetron due to a change in the standing waves on the rf lines.

magnetron pushing—The shift in the frequency of a magnetron caused by faulty modulator operation.

magnetron rectifier—A gas-tube rectifier in which the electron stream is controlled by an optical element or instrument instead of by heated electrodes.

magnet steel—A special steel used in permanent magnets because of its high retentivity. In addition to

steel, it also contains tungsten, cobalt, chromium, and manganese.

magnet tester—See magnet meter.

magnetor—See magnetic modulator.

magnet wire—1. An insulated copper wire used for winding the coils of electromagnets. 2. Soft, insulated copper wire in the range of sizes used for winding relay and transformer coils. Usually has enamel insulation.

magnification ratio—The ratio of the size of an image produced by a lens to the size of the source.

magnified sweep—In an oscilloscope, a sweep whose time per division has been decreased by amplification of the sweep waveform rather than by changing the time constants used to generate it.

Magnistor—A saturable reactor for controlling electrical pulses or sine waves having frequencies of 100 kHz to 30 MHz and power levels ranging from microwatts to tens of watts.

magnitude—1. Size; the quantity assigned to one unit so that it may be compared with other units of the same class (i.e., the ratio of one quantity to another). 2. The size of a quantity irrespective of its sign. For example, +10 and -10 have the same magnitude.

magnitude-controlled rectifier—A type of rectifier circuit in which a thyatron is used as the rectifying element. The load current is controlled by varying the bias on the grid of the thyatron.

mag-slip—A British term for synchro (i.e., a synchronous device such as the selsyn, autosyn, motortorque, and generator).

mailbomb—Sending a large amount of e-mail to a person's mailbox with the intent of harassing the person.

mailbox—1. A computer location in a RAM storage area reserved for data addressed to specific peripheral devices as well as other microprocessors in the immediate environment. (Such an arrangement enables the coordinator CPU and the supplementary microprocessors to transfer data among themselves in an orderly fashion with minimal hardware.) 2. A system data structure that handles task communication. Tasks send messages to and receive messages from mailboxes. 3. A disk storage area assigned to a network user for receipt of e-mail messages.

mailer—A cassette or very small reel of tape sold in a cardboard box printed with name and address blanks, for sending through the mail.

mailer-daemon—An automated program that returns Internet mail if it is undeliverable for one reason or another. Usually, returned mail is the result of addressing the mail incorrectly.

mail merge—Taking information from a database and inserting it in a word processing document. Frequently used to create "personalized" form letters from mailing lists.

main anode—The anode that conducts the load current.

main bang—The transmitted pulse of a radar system.

main bonding jumper—The connection between the grounded circuit conductor and the equipment grounding conductor at the service.

main control unit—Transmitter or receiver controls for energizing, adjustment, etc., of the transmitter or receiver, but not for operating it while on the air.

main disconnect—The means provided in an electrical system to disconnect all conductors in a building from the service-entrance conductors. The means may consist of one or more, but not to exceed six, closely grouped switches or circuit breakers.

main distributing frame—In a telephone central office, a distributing frame, on one section of which terminate permanent outside lines, and on another section

of which terminate the subscriber-line multiple cabling, trunk multiple cabling, etc., used for associating an outside line with any desired terminal in such a multiple or with any other outside line. The main distributing frame usually carries the central-office protective devices and serves as a test point between line and office.

main entrance panel—A single enclosure housing the main disconnect, main overcurrent protection devices, branch circuit overcurrent devices, and branch circuit and feeder distribution means.

main-exciter—An exciter that supplies energy for the field excitation of another exciter.

mainframe—Also called central processing unit. 1. The central processor of the computer system. It contains the main storage, arithmetic unit, and special register groups. 2. The CPU of a computer plus the input/output unit and memory. As distinguished from peripheral equipment. 3. The main part of a computer system. 4. A large computer that stores information and distributes it to a network of micro- or minicomputers. Mainframes have largely given way to workstations, which serve fewer users and usually have the CPU and the terminal at the same location, but can be accessed remotely.

main gap—The conduction path between the principal cathode and anode.

main memory—See internal storage, 1.

main power—Power supplied to a complete system from a line.

mains—Interior wires extending from the service switch, generator bus, or converter bus to the main distribution center.

main service panel—The main electrical switch or circuit breaker and the circuit panel box that houses the circuit breakers or fuses for a branch circuit.

mains line—British word for ac power line.

main station—1. A telephone station that has a distinct call number and a direct connection to a central office. 2. With respect to leased lines for customer equipment, the main point of interfacing of such equipment with the logic loop.

main storage—Usually the fastest storage device of a computer and the one from which instructions are executed.

main sweep—The longest-range scale available on some fire-control radars.

maintainability—A characteristic of design and installation expressed as the probability that an item will be retained in or restored to a specified condition within a given period when the maintenance is performed in accordance with prescribed procedures and resources.

maintained contact—Switch actuator that remains in a given position until it is actuated to another position, which is also maintained until further action.

maintained contact switch—A switch that remains in a given condition until actuated to another condition, which is also maintained until further actuation.

maintained switch—A switch that remains at the operated circuit condition when the actuating force is removed. It returns to the normal circuit condition, or moves to another position, when actuated a second time.

maintaining voltage—The voltage across a glow lamp after breakdown occurs.

maintenance—1. All procedures necessary to keep an item in, or restoring it to, a serviceable condition, including servicing, repair, modification, modernization, overhaul, inspection, etc. 2. See file maintenance.

maintenance time—Time used for preventive and corrective maintenance of hardware.

major-apex face—In a natural quartz crystal, any one of the three larger sloping faces extending to the apex

(pointed) end. The other three are called the minor-apex faces.

major cycle—1. In a memory device that provides serial access to storage positions, the time interval between successive appearances of a given storage position. 2. A number of minor cycles.

major defect—A defect that could result in failure or significantly reduce the usability of a unit for its intended purpose.

major face—Any one of the three larger sides of a hexagonal quartz crystal.

major failure—1. A noncritical failure that can degrade the system performance due to cumulative tolerance buildup. 2. A malfunction in a system that, while not causing complete breakdown, causes it to function uselessly.

major items—Items and components of communications electronics equipment that are designed to perform a specific function (e.g., radio, radar sets, transmitters, receivers, modulators, amplifiers, and assemblies) and for which the procurement and supply lead times are such that the items must be programmed and procured to be available at a given time. A programming term.

majority—A logical operator with the property that if P, Q, R, etc. are statements, the majority of P, Q, R, ... is true if more than half the statements are true, and false if half or fewer are true.

majority carrier—The predominant carrier in a semiconductor. Electrons are the majority carrier in n-type semiconductors, since there are more electrons than holes. Likewise, holes are the majority carrier in p-type semiconductors, since they outnumber the electrons.

majority-carrier contact—An electrical contact across which the ratio of majority-carrier current to applied voltage is substantially independent of the voltage polarity but the ratio of minority-carrier current to applied voltage is not.

majority emitter—The transistor electrode from which the majority carriers flow into the interelectrode region.

majority gate—A logic element whose output is true if more than half of the inputs are true, but whose output is false for other input conditions.

major lobe—1. The antenna lobe in the direction of maximum energy radiation or reception. 2. The largest of the several lobes, or three-dimensional petals, that represent the radiation pattern of a directional antenna. The lobe in the direction of preferred reception or transmission.

major loop—A continuous network composed of all the forward elements and the primary feedback elements of a feedback control system.

major relay station—A tape relay station to which two or more trunk circuits are connected in order to provide an alternate route or to meet command requirements.

make—1. The closing of a relay, key, or other contact. 2. A closed circuit or off-hook condition as determined by the dial of a telephone set.

make-before-break—The action of closing a switching circuit before opening another associated circuit.

make-before-break contacts—1. Double-throw contacts so arranged that the moving contact establishes a new circuit before disrupting the old one. 2. Movable contact that makes the next circuit before breaking the first circuit. 3. A set of three contacts on a key or relay, so arranged that contact A makes with contact C before breaking from contact B.

make-before-break switch—*See* shorting switch.

make-break contacts—Also called continuity-transfer contact. A contact form of a relay, in which one contact closes connection to another contact and then opens its prior connection to a third contact.

make-break electrode—In a mercury switch, that electrode which serves the function of making and breaking contact with the mercury pool to close or open the electrical circuit.

make contact—1. A contact that closes a circuit upon operation of the device of which the contact is a part. 2. Contact that closes when a key or relay is operated. *See also* normally open contact.

make percent—In pulse testing, the length of time, in comparison with the duration of the test signal, that a circuit stands closed.

make-up time—That portion of available time used for reruns made necessary by malfunctions or mistakes that occurred during a previous operating time.

male—Adapted so as to fit into a matching hollow part.

male contact—A contact located in the insert or body of a connector in such a way that the mating portion of the contact extends into the female contact. It is similar in function to a pin contact.

malfunction—Any incorrect functioning within electronic, electrical, or mechanical hardware. *See also* error, 3; fault.

malware—Malicious software, such as worms, viruses, and trojan horses.

Manchester encoding—A coding scheme used with several LANS. Manchester encoding has a logic transition in the center of each bit. A positive transition indicates a logical 1, and a negative transition indicates a logical 0.

mandrel—Also called an arbor. Shaft on which wound capacitors are wound.

mandrel test—A test used to determine the flexibility of insulation. In it a wire, with or without previous stretch, is wrapped around a mandrel.

manganin—An alloy wire used in precision wire-wound resistors because of its low temperature coefficient of resistance.

manipulated variable—The one variable (condition, quantity, etc.) of a process that is being controlled. The process can be controlled through manipulations of this variable.

man-made interference—A type of electromagnetic interference generated by electric motors, communication and broadcast transmitters, fluorescent lighting, and other electrical and electronic systems that radiate spurious signals.

man-made noise—1. High-frequency noise signals caused by sparking in an electric circuit. 2. Noise created by voltages that result from the use of machinery, such as electric motors and internal-combustion engines.

man-made static—High-frequency noise signals created by sparking in an electric circuit. When picked up by radio receivers, it causes buzzing and crashing sounds from the speaker.

manpack—Also called packset. A portable radio-transmitting/receiving device that can be carried easily in a harness by a man.

man-rem—The absorbed dose of 1 rem by one human; also, the measure of population dosage, calculated by adding the doses received by each member of the population.

manual—1. Hand operated. 2. In an organ, a group of keys played with the hand. In two-manual organs the upper manual, also referred to as the solo or swell manual, is normally used to play the melody. The lower manual, also referred to as the accompaniment manual or great

manual, is normally used to play the accompaniment. 3. Operated by mechanical force applied directly by human intervention.

manual analysis—Also called manual test programming. The generation of input and output test patterns by a test engineer or technicians who study the function or structure of a logic circuit.

manual central office—A central office of a manual telephone system.

manual control—1. The opening or closing of switches by hand. 2. The direction of a computer by means of manually operated switches.

manual controller—An electric controller in which all but its basic functions are performed by hand.

manual dimmer—A dimmer in which the only linkage between the control lever and the moving electrical contact that conducts the electrical power is mechanical.

manual direction finder—A radio compass that uses a rotatable loop that is operated manually.

manual exchange—A telephone exchange in which the lines are connected to a switchboard and interconnections are controlled by an operator.

manual input—1. The entry of data into a system by hand at the time of processing. 2. Direct computer entry by means of manual intervention, or drum entry of manual data through card machines.

manual operation—Data processing in a system by means of direct manual techniques.

manual preset timer—A manual start timer, the cycle of which is initiated by turning a pointer to the desired setting.

manual rate-aided tracking—Radar tracking of individual targets by means of circuits that compute the velocity from manually inserted position fixes.

manual reset—A qualifying term used to indicate that a relay may be reset manually after an operation.

manual ringing—A method of ringing a telephone. The key must be held down for the ringing to continue. Nor does it stop when the receiver is lifted off the hook, unless the caller releases the key.

manual single play—A turntable operation in which records are played one at a time, and the arm is placed on the record and removed again manually.

manual start timer—An interval timer on which each cycle must be manually started at the timer.

manual switch—A switch that is actuated by an operator.

manual switchboard—A telephone switchboard in which the operator makes connections manually with plugs and jacks or with keys.

manual switching—A characteristic of a circuit breaker permitting manual opening and closing of the circuit by operation of the actuator.

manual telegraphy—Telegraphy in which an operator forms the individual characters of the alphabet in code.

manual telephone—A telephone without push button or rotary dial that rings the attendant automatically when the receiver is lifted.

manual telephone set—A set not equipped with a dial for securing the number to be called. Instead, lifting the receiver alerts the switchboard operator, who then connects the caller to the person being called.

manual telephone system—A system in which telephone connections between customers are ordinarily established manually by telephone operators, in accordance with orders given verbally by the calling parties.

manual test programming—See manual analysis.

manual tuning—Rotation by hand of a knob on a radio receiver to tune in a desired station.

manufacturing holes—See pilot holes.

manuscript—A form of storage medium, such as programming charts, in which is contained raw information in a sequential form suitable for translation.

MAR—Abbreviation for memory address register.

Marconi antenna—An antenna system in which one end of the signal source is connected to a radiating element and the other end is connected to ground.

Marconi antenna.

margin—1. The difference between an actual operating point and the point or condition where a failure to operate properly will occur. 2. Also called range or printing range. In telegraphy, the interval between limits on a scale, usually arbitrary, in which printing is error-free. 3. The distance that the electrode foil is indented from the edge of the dielectric when a capacitor is wound.

marginal—Operating at the border of permissible limits of voltage, current, distortion, etc. When operation is marginal, a very small impairment can cause the device or system to fail.

marginal checking—Also called marginal testing. Preventive maintenance in which certain operating conditions (e.g., supply voltage or frequency) are varied from normal in order to locate defects before they become serious.

marginal relay—A relay with a small margin between its nonoperative current value (maximum current applicable without operation) and its operative value (minimum current that operates the relay).

marginal testing—See marginal checking.

margin-punched card—A card in which holes representing data are punched only on the border, with the center left free for written or printed information.

marine broadcast station—A coastal station that regularly broadcasts the time and meteorological and hydrographic information.

marine radiobeacon station—A radionavigation land station whose emissions are used to determine the bearing or direction of a ship in relation to the marine radiobeacon station.

maritime mobile service—The radio service in which ships communicate with each other or with coastal and other land stations on specified frequencies.

maritime radionavigation service—A radio service intended to be used for the navigation of ships.

mark — 1. In telegraphy, the closed-circuit condition, i.e., the signal that closes the circuit at the receiver to produce a click of the sounder or to print a character on a teletypewriter. 2. The presence of signal. A mark impulse is equivalent to a binary 1. 3. A term that originated with telegraphy to indicate a closed key condition. Present usage implies the presence of current or carrier on a circuit or the idle condition of a teletypewriter. It also indicates the binary digit 1 in computer language. *See* flag. 4. In RTTY applications, the mark is one of two states. The mark is the condition characterized by a closed circuit. The space, the other state, is characterized by an open-circuit condition.

mark and space impulses — In neutral operation of a teletypewriter system, the mark impulse is the closed-circuit signal, and the space impulse is the open-circuit signal. In other than neutral operation, the mark impulse is the circuit condition that produces the same result in the terminal equipment that a mark impulse produces in neutral operation. Similarly, the space impulse is the circuit condition that produces the same result in the terminal equipment that a space impulse produces in neutral operation.

marker — Also called marker beacon. A radio navigational aid consisting of a transmitter that sends a signal to designate the small area around and above it.

marker antenna — The transmitting antenna for a marker beacon.

marker beacon — *See* marker.

marker generator — An rf generator that injects one or more pips of specific frequency onto the response curve of a tuned circuit being displayed on the screen of a cathode-ray oscilloscope.

marker pip — The inverted V (Δ) or spot of light used as a frequency index mark in cathode-ray oscilloscopes for alignment of TV sets. It is produced by coupling a fixed-frequency oscillator to the output of a sweep-driven signal generator.

marker thread — A colored thread laid parallel and adjacent to the strands of an insulated conductor that identifies the wire manufacturer and often the specification under which the wire was constructed.

marking-and-spacing intervals — In telegraphy, the intervals corresponding to the closed and open positions, respectively, of the originating transmitting contacts.

marking bias — Bias that affects the results in the same direction they are affected by marking current.

marking current — The magnitude and polarity of line current when the receiving mechanism is in the operated condition.

marking pulse — The signal interval during which the selector unit of a teletypewriter is operated.

marking wave — Also called keying wave. In telegraphy, the emission while the active portions of the code characters are being transmitted.

mark sense — 1. To mark a position on a punch card, using a special pencil that leaves an electrically conductive deposit for later conversion to machine punching. 2. A mechanized technique of punching data into computer cards. A graphite line positioned on the card is read electronically and converted into holes by special equipment.

mark-sense card — A card designed to permit data to be entered on it with an electrographic pencil.

mark sensing — A technique for detecting special pencil marks entered in special places on a card and automatically translating the marks into punched holes.

mark-to-space transition — The change from a marking impulse to a spacing impulse.

marshalling sequence — *See* collating sequence, 1.

maser — Acronym for microwave amplification by stimulated emission of radiation. 1. A low-noise microwave amplifier in which a signal is boosted by changing the energy level of a gas or crystal (commonly, ammonia or ruby, respectively). 2. A means of focusing a stream of particles, which concentrates only on the high-energy particles. These are passed into a resonator that is resonating at the radiation frequency of the particles. The particles are raised to a strong oscillation in this state and can be used for control purposes. By reducing the flow of particles to the resonator to maintain oscillations, it can be used as an amplifier. (There are many other applications.) 3. Device for amplifying a microwave frequency signal by stimulated emission of radiation—i.e., the weak microwave signal causes electrons in an atom to change orbit in such a manner as to emit an amplified signal of the same frequency as the weak signal. 4. Amplification by a low-noise radio-frequency amplifier in which an input signal stimulates emission of energy stored in a molecular or atomic system by a microwave power supply.

mask — 1. A frame mounted in front of a television picture tube to limit the viewing area of the screen. 2. A device (usually a thin sheet of metal that contains an open pattern) used to shield selected portions of a base during a deposition process. 3. A device used to shield selected portions of a photosensitive material during photographic processing. 4. A logical technique in which certain bits of a word are blanked out or inhibited. 5. Template used to etch circuit patterns on semiconductor wafers. Images of the circuit patterns are produced on glass or metal photographically. The mask is then used to control the diffusion process, plus metallization. 6. A transparent (glass or quartz) plate covered with an array of patterns used in making integrated circuits. Each pattern consists of opaque and transparent areas that define the size and shape of all circuit and device elements. The mask is used to expose selected areas of photoresist, which define areas to be etched. Masks may use emulsion, chrome, iron oxide, silicon, or other material to produce the opaque areas. 7. Thin metals or other materials with an open pattern designed to mask off or shield selected portions of semiconductors or other surfaces during deposition processes. There also are photomasks or optical masks for contact or projection printing of wafers; these may use an extremely flat glass substrate with iron oxide, chrome, or emulsion coating. There also are thick-film screen masks. 8. The photographic negative that serves as the master for making thick-film screens and thin-film patterns. 9. The pattern, usually "printed" on glass, used to define areas of the chip or wafer. Masks are used for the diffusion, oxidation, and metallization steps used in manufacturing of semiconductors. 10. To hide, to obscure, to make less noticeable. For example, as noise masks crosstalk. 11. A material applied to enable selective etching, etching, plating, or the application of solder to a printed board. Also, the surface on which the master artwork of the circuit pattern is projected. 12. A thin steel arrangement with fine holes (shadow mask) or stripes (slot mask) that concentrates the electron beam at points on the CRT.

masked diffusion — The use of a mask pattern to obtain selective impregnation of portions of a semiconductor material with impurity atoms.

masked ROM — A regular read-only memory (ROM) produced by the usual masking process. (Contrasted with a PROM.)

masking — The process by which a sound is made audible by the addition of a second sound called the masking sound. The unit of measurement is usually the decibel.

masking audiogram—A graphical representation of the amount of masking by a noise. It is plotted in decibels as a function of the frequency of the masked tone.

mask microphone—A microphone designed for use inside an oxygen or other respiratory mask.

mask-programmed—A semiconductor device, most often a read-only memory, that is permanently programmed as a step in its manufacture. In contrast, *field-programmed* applies to memory devices that are programmed after manufacture.

mask set—A set of plates, usually glass, that are used to transfer a device topology in sequence to a wafer during fabrication.

Masonite—Trade name of the Masonite Corp. Fiberboard made from steam-exploded wood fiber. Its highly compressed forms are used for panels in electrical equipment.

mass—1. The quantity of matter in an object. It is equal to the weight of a body divided by the acceleration due to gravity. 2. The bulk of matter, though not necessarily equal to its weight. 3. A mechanical unit whose electrical analog is inductance.

mass data—A larger amount of data than can be stored in the central processing unit of a computer at any one time.

mass-memory unit—A drum or disk memory that provides rapid-access bulk storage for messages being held until outgoing channels are available.

mass properties—Calculation of physical engineering information about a part, e.g., perimeter, area, volume, weight, and moments of inertia.

mass radiator—A spark radiator that generates a low-level broadband signal extending into and above the EHF band. Arcing occurs between fine metal particles suspended in a liquid dielectric.

mass spectrometer—An instrument that permits rapid analysis of chemical compounds. It consists of a vacuum tube into which a small amount of the gas to be studied is admitted. The gas is ionized by the electrons emitted from the cathode and speeded up by an accelerating grid. An electric field draws the ions out of the ionizing chamber. They are then sent through electric and magnetic fields that sort them according to their ratios of mass to charge.

mass spectrum—The spectrum obtained by deflecting a beam of electrons with an electric or magnetic field as they emerge from a tube containing a small quantity of the gas being investigated. The amount a particle is deflected depends on the ratio of its mass to its atomic charge. Hence, every element has a characteristic mass-spectrum line.

mass storage—1. Refers to hardware devices providing massive amounts of online secondary storage, generally using strips of inexpensive magnetic media that can be accessed randomly, but with slower access times than those of conventional tape or disk devices. 2. Refers to peripheral devices into which programs and data are stored for immediate action. 3. In a computer, secondary, slower memory for bulky files. Mostly floppy disk, cassette, or tape.

mass storage device—Any device used to provide relatively inexpensive storage for large amounts of data.

mass termination—The simultaneous termination of several or all conductors of a cable. This process generally uses terminals that pierce the insulation without stripping to cold-flow mate with the conductors and form a gas-tight metal-to-metal joint. See insulation displacement connector.

mast—The pole on which an antenna is mounted.

master—1. The mold from which other disc recordings are cast. It is made by electroforming from a disc recording, and is a negative of the disc (i.e., has ridges instead of grooves). 2. An original, or first special copy, of a recorded performance from which other copies may be made. 3. An original recording, made directly from recording microphones. A disc master is the lacquer original, usually cut from a tape from which stampers are made for vinyl pressings. 4. An element of a system that controls or initiates the action or responses of the other elements of the system.

master antenna television—Abbreviated MATV.

1. An antenna system that serves a concentration of television sets, such as in apartment buildings, hotels, or motels. 2. Broadcast receiving stations that use one or more high-quality centrally located UHF and/or VHF antennas that relay their signals to many televisions in a local apartment/condo or group-housing complex.

master brightness control—In a color television receiver, a variable resistor that adjusts the bias level on all three guns in the picture tube at the same time.

master clock—1. In a computer, the primary source of timing signals. 2. A very accurate timer with an absolute time reference, providing controlled power to drive slave or auxiliary timers and display units. May also provide correcting pulses for slave devices.

master contactor—A device that is generally controlled by a master element or equivalent, and the necessary permissive and protective devices, and which serves to make and break the necessary control circuits to place an equipment into operation under the desired conditions and to take it out of operation under other or abnormal conditions.

master control—1. In a studio, a central point from which sound or television programs are switched to one or more destinations. 2. An application-oriented routine usually applied to the highest level of a subroutine hierarchy.

master die—A substrate that contains unconnected active and passive elements in a predetermined pattern. Connection pads for each element and subelement are provided, and a variety of circuits may be obtained by appropriate choices of intraconnection patterns.

master drawing—A drawing showing the dimensional limits or grid locations applicable to any or all parts of a printed circuit, including the base.

master drive—A drive that determines the reference input for one or more follower drives.

master element—The initiating device, such as a control switch, voltage relay, float switch, etc., that serves either directly or through such permissive devices as protective and time-delay relays to place an equipment in or out of operation.

master file—In a computer, a file of relatively more permanent information that is usually updated periodically.

master gain control—1. An amplifier control that permits adjusting the gain of two or more channels simultaneously. 2. Control of overall gain of an amplifying system as opposed to varying the gain of several individual inputs.

master instruction tape—A computer magnetic tape on which are recorded all programs for a system of runs.

master layout—The original layout of a circuit.

master mask—A chrome mask of a complete wafer's multiple images. It is used either in projection printing on a wafer or to contact-print additional masks.

master oscillator—1. In a transmitter, the oscillator that establishes the carrier frequency of the output.

2. An oscillator that controls or provides modulator drive frequencies for a number of channels or channel groups.

master-oscillator power amplifier— Abbreviated MOPA. An oscillator followed by a radio-frequency buffer-amplifier stage.

master pattern—An accurately scaled pattern that is used to produce the printed circuit within the accuracy specified in the master drawing.

master plates— See photomask, 4.

master processor—The main processor in a master-slave configuration.

master reticle—A reticle plate properly aligned in a reticle frame and sealed in place. The master reticle is inserted into a photorepeater to make the final-sized photomask. Used in the production of monolithic circuits.

master routine— See subroutine, 2.

master scheduler—The control-program function that responds to operator commands, initiates requested actions, and returns information that is requested or required; the overriding medium for control of the use of the computing system.

master-slave—1. A binary element consisting of two independent storage stages arranged with a definite separation of the clock function to enter information to the master stage and to transfer it to the slave stage. 2. A configuration in which one system, the master, always has control over another system, the slave.

master-slave flip-flop—A circuit that contains two flip-flops, a master and a slave. The master flip-flop receives information on the leading edge of a clock pulse, and the slave (output) flip-flop receives information on the trailing edge of the clock pulse.

Master-slave J-K flip-flop.

master slice—A silicon wafer containing 30 or more groups of components. The elements can be interconnected with paths of aluminum to form desired circuits. The wafer is then diced into single devices.

master stamper—A master from which phonograph records are pressed.

master station—1. The radio station to which the emission of other stations of a synchronized group are referred. 2. In a hyperbolic navigation system, the one of a pair of transmitting stations that controls the transmission of the other (slave) station in the pair and maintains the time relationship between the pulses emitted from the two stations. 3. The device that controls all other devices for the purpose of organizing communications over a transmission line.

master switch—A switch located electrically ahead of a number of other switches.

master synchronization pulse—A pulse distinguished from other telemetering pulses by its different

amplitude and/or duration and used to indicate the end of a sequence of pulses.

master TV system—A combination of components for providing multiple TV set operation from one antenna.

master wafer—A processed semiconductor wafer with unconnected active and passive circuit elements located in a standardized pattern. Different integrated circuits may be synthesized by using various interconnection paths.

MAT—Acronym for microalloy transistor.

match—1. The similarity or equality of one thing to another. 2. To compare two or more items of data for identity.

matched filter—An optimum filter for separating a waveform of known shape from random perturbing noise.

matched impedance—The condition that exists when two coupled circuits are adjusted so that the impedance of one circuit equals the impedance of the other.

matched load—A device used to terminate a transmission line or waveguide so that all the energy from the signal source will be absorbed.

matched power gain—That power gain which is obtained when the impedance of the load is matched to the effective output impedance of the amplifier to which the load is connected.

matched pulse intercepting—Technique used in intercepting calls on party lines in a terminal-per-line office. A ground pulse is matched in time with the particular ringing frequency of the intercepted station.

matched symmetrical transistor—A special case of the bidirectional transistor in which not only are the requirements for a symmetrical transistor met, but actual matching specifications are also given. See also symmetrical transistor.

matched termination—A termination that causes no reflected wave at any transverse section of the transmission line. Its impedance is equal to the characteristic impedance of the line.

matched transmission line—A transmission line along which there is no wave reflection.

matched waveguide—A waveguide along which there is no reflected wave.

matching—1. Connecting two circuits or parts together with a coupling device in such a way that the maximum transfer of energy occurs between the two circuits, and the impedance of either circuit will be terminated in its image. 2. The connection of a component's output to an input that provides the recommended value of load, or termination impedance. 3. Obtaining like impedances to provide a reflection-free transfer of signal.

matching diaphragm—A window consisting of an aperture (slit) in a thin piece of metal, placed transversely across a waveguide; used as a matching device. The orientation of the slit (whether parallel to the long or short dimensions of the waveguide) determines whether it is respectively capacitive or inductive.

matching impedance—The impedance value that must be connected to the terminals of a signal-voltage source for proper matching.

matching plate—In waveguides, a diaphragm used for matching.

matching stub—A device placed on a radio-frequency transmission line to vary its electrical length and hence its impedance.

matching transformer—A transformer used for matching impedances.

mate—Joining of two connector halves, or of a cable to a connector.

material dispersion—Broadening of light impulses arising from wavelength-dependent differential delay of light in a waveguide material.

material system—The designation of the number of basic metals (e.g., silver-antimony-telluride) making up thermoelectric materials.

math coprocessor—A special chip that is added to a computer to handle advanced mathematic functions, thereby freeing up the processing power of the main CPU.

mathematical check—A check making use of mathematical identities or other properties.

mathematical logic—Also called symbolic logic. Exact reasoning concerning nonnumerical relations by using symbols that are efficient in calculation.

mathematical model—1. The general characterization of a process, object, or concept in terms of mathematics that enables the relatively simple manipulation of variables to be accomplished in order to determine how the process or concept would behave in different situations. 2. A mathematical representation that simulates the behavior of a process, device, or concept. 3. A mathematical equation that can be used to numerically compute a system's response to a particular input.

mating face—See interface.

matrices—Plural of matrix.

matrix—1. A coding network or system in a computer. When signals representing a certain code are applied to the inputs, the output signals are in a different code. 2. In electronic computers, any logical network whose configuration is a rectangular array of intersections of its input-output leads, with logic elements connected at some of these intersections. The network usually functions as an encoder or decoder. 3. A computer network or system in which only one input is excited at a time and produces a combination of outputs. 4. In a color TV circuit, the section that combines the I, Q, and Y signals and transforms them into individual red, green, and blue signals that are applied to the picture-tube grids. 5. A rectangular array of scalar quantities, usually numbers or letters used to represent numbers. Rectangular array means that the elements are arranged into definite rows and columns. 6. An orderly two-dimensional array. An arrangement of circuit elements, such as wires, relays, diodes, etc., that can transform a digital code from one type to another. 7. The terminology applied to the several methods for encoding four channels onto two channels for later recovery back to four channels. Also referred to as 4-2-4. The actual electronics used to encode into two channels or decode back to four are known as matrixing electronics. 8. A rectangular array of elements, in cross-match fashion. Used to describe memory organization, character formation, diode layouts, and so forth. 9. A general process whereby several signals can be added together for recording or transmission on fewer channels, and later retrieved through a complementary process. 10. A mathematical array having height, width, and sometimes depth, into which collections of data may be stored and processed.

matrixer—Also called matrix unit. A device that transforms the color coordinates, usually by electrical or optical means.

matrixing electronics—See matrix, 7.

matrix life test—A test in which each test condition has two components. For example, in transistor matrix life testing each life-test condition is represented by an ambient temperature and a power dissipation. At each stress level of temperature, there are several dissipations; and at each stress level of dissipation, there are several temperatures. The test conditions are placed into blocks or groups.

matrix line printer—A printer in which each character is composed of a matrix of dots.

matrix printer—A printer that uses an impact process in which the desired character is created from small dots.

matrix storage—Storage in which the elements are arranged in such a way that access to any location requires the use of two or more coordinates, as, for example, in cathode-ray-tube storage and core storage.

matrix switcher—A combination or array of electromechanical or electronic switches that routes a number of signal sources to one or more designations.

matrix unit—See matrixer.

mat switch—A flat area switch used on open floors or under carpeting. It may be sensitive over an area of a few feet or several square yards.

matter—Any physical entity—i.e., having mass.

Matteucci effect—The ability of a twisted ferromagnetic wire to generate a voltage as its magnetization changes.

MATV—Abbreviation for master antenna television system.

max—Abbreviation for maximum.

maxima/minima—In radar, regions of maximum and minimum return from the transmitted pulse caused by additive and subtractive combinations of the direct and reflected wave. A plot of this data is usually known as a null pattern or fade chart.

maximize—In a Windows program, enlarging a window to its largest size, usually filling the entire screen.

maximum—Abbreviated max. The highest value occurring during a stated period.

maximum average power output—In television, the maximum radio-frequency output power, averaged over the longest repetitive modulation cycle.

maximum deviation sensitivity—Under maximum system deviation, the smallest signal input for which the output distortion does not exceed a specified limit.

maximum dissipation—The maximum average power a device can dissipate during operation while still remaining within published life specifications.

maximum frequency of oscillation—The maximum frequency at which a vacuum tube or transistor can be made to oscillate under specified conditions. This approximates to the frequency at which the maximum available power gain has decreased to unity.

maximum keying frequency—In a facsimile system, the frequency (in hertz) equal to half the number of critical areas of the subject copy scanned per second.

maximum luminous efficiency—The greatest luminosity possible for a specified chromaticity.

maximum luminous reflectance—The greatest luminous reflectance possible for a specified chromaticity.

maximum luminous transmittance—The greatest luminous transmittance possible for a specified chromaticity.

maximum modulating frequency—In a facsimile system, the maximum scanning frequency process that can be transmitted without degrading the recorded copy.

maximum output—The highest average output power into a rated load, regardless of distortion.

maximum overshoot—The maximum amplitude deviation from the average of the steady-state values that exist immediately before and after the transient.

maximum peak plate current—The highest instantaneous plate current a tube can safely carry.

maximum percentage modulation—The highest percentage of modulation permitted in a transmitter without producing excessive harmonics in the modulating frequency.

maximum permeability—The highest permeability reached as induction or magnetization is increased.

maximum power transfer theorem—The maximum power will be absorbed by one network from another joined to it at two terminals, when the impedance of the receiving network is varied, if the impedances (looking into the two networks at the junction) are conjugates of each other.

maximum record level—In direct recording, the amount of record-head current required to produce 3-percent third-harmonic distortion of the reproduced signal at the record-level set frequency. Such distortion must result from magnetic-tape saturation, not from electronic circuitry.

maximum response speed—The maximum pulse frequency that can be applied to a stepper motor at random and result in synchronized steps. The motor must not miss in step while operating within this range.

maximum retention time—The maximum time interval between writing into a storage element of a charge storage tube and reading an acceptable output.

maximum saturation—The highest value of saturation possible for a specified hue.

maximum sensitivity—The smallest signal input that produces a specified output.

maximum signal level—In an amplitude-modulated system, the level corresponding to copy black or copy white—whichever has the higher amplitude.

maximum sound pressure—For any given cycle of a periodic wave, the maximum absolute value of the instantaneous sound pressure. The most common unit is the microbar.

maximum storage time—In a storage tube, the length of time after writing during which an acceptable output can be read. *See also* maximum usable viewing time.

maximum system deviation—In a frequency-modulation system, the greatest permissible deviation in frequency.

maximum torque—*See* pull-out torque.

maximum undistorted output—Also called maximum useful output. The maximum power an amplifier can deliver without producing excessive harmonics.

maximum usable frequency—Abbreviated MUF. 1. In radio transmission by ionospheric reflection, the highest frequency that can be transmitted by reflection from regular ionized layers. 2. The highest frequency at which the ionosphere reflects signals to earth. Any signals of higher frequency than the MUF penetrate the ionosphere and enter space.

maximum usable viewing time—Also called maximum storage time. The length of time during which the visible output of a storage tube can be viewed, without rewriting, before a specified decay occurs.

maximum useful output—*See* maximum undistorted output.

maximum working voltage—The maximum voltage stress (dc or ac) that may be applied to a component under specified conditions of use.

maximum writing rate—The maximum spot speed that produces a line of specified density on a photographic negative or on the screen of a cathode-ray tube.

maxterm form—A function expanded into a product of sums, such as $(A + B)(C - D)(E + F)$.

maxwell—The cgs electromagnetic unit of magnetic flux, equal to 1 gauss per square centimeter, or one magnetic line of force.

Maxwell bridge—A four-arm ac bridge normally used for measuring inductance in terms of resistance and capacitance (or capacitance in terms of resistance

and inductance). One arm has an inductor in series with a resistor, and the opposite arm has a capacitor in parallel with a resistor. The other two arms normally are nonreactive resistors. The balance is independent of frequency.

Maxwell bridge.

Maxwell inductance bridge—A four-arm ac bridge for comparing inductances. Two adjacent arms have inductors, and the other two arms usually have nonreactive resistors. The balance is independent of frequency.

Maxwell mutual-inductance bridge—A four-arm ac bridge for measuring mutual inductance in terms of self-inductance. Mutual inductance is present between the supply circuit and the arm that includes one coil of the mutual inductor. The other three arms normally are nonreactive resistors. The balance is independent of frequency.

Maxwell's equations—Fundamental equations, developed by J. C. Maxwell, for expressing radiation mathematically and describing the condition at any point under the influence of varying electric and magnetic fields.

Maxwell's law—A movable portion of a circuit will always travel in the direction that gives maximum flux linkages through the circuit.

Maxwell triangle—A graph that defines the chromaticity values of a color in terms of three coordinates.

maxwell-turn—A unit of magnetic linkage equal to one magnetic line of force passing through one turn of a circuit.

mayday—International distress call for radiotelephone communication. It is derived from the French *m'aidez*, meaning "help me."

Mbps—Millions of bits per second (bps).

mc—Abbreviation for megacycle—an obsolete term superseded by MHz (megahertz).

MCM—1. Abbreviation for multichip module. An electronic package containing several chips on a single substrate. 2. *See* Monte Carlo method.

McNally tube—A velocity-modulated vacuum tube that produces low-power UHF oscillations. It is used as a local oscillator in some radar receivers.

MCW—Abbreviation for modulated continuous wave.

MD—Abbreviation for mini-disc.

m-derived filter—A type of constant-k filter in which the constant-k elements are multiplied by the factor m or a function of m . Generally, the m-derived filter has more elements and provides sharper cutoff and more uniform attenuation in the pass region. It may provide high-pass, low-pass, bandpass, or band-stop filtering action.

m-derived L-section filter—A reactance network derived from the prototype L-section filter, so that the image-transfer coefficient and one image impedance are changed, but the other image impedance is left unchanged.

MDI—Abbreviation for magnetic direction indicator.

M-display—See M-scan.

MDS—Abbreviation for microcomputer development system.

M-DVD—Abbreviation for magnetic digital versatile disc. A 3.5-inch removable storage medium with 2.1 gigabytes of capacity which is achieved by using magneto-resistive technology.

Meacham-bridge oscillator—A crystal oscillator in which the crystal forms one arm in a bridge so as to obtain effective multiplication of the actual Q of the crystal.

meaconing—1. The interception and rebroadcast of beacon signals. They are rebroadcast on the received frequency to confuse enemy navigation. As a result, aircraft or ground stations are given inaccurate bearings. 2. The clandestine generation or retransmission of a radionavigation signal in order to confuse navigation.

mean—1. The arithmetic middle point of a range of values, obtained by adding the smallest value to the largest value and dividing that sum by two. 2. The arithmetic average of a group of values.

mean absolute deviation—Abbreviated MAD. The average of the absolute values of the deviations of some observed value from some expected value. MAD can be calculated based on observations and the arithmetic mean of those observations.

mean carrier frequency—The average carrier frequency of a transmitter (corresponding to the resting frequency in a frequency-modulated system).

mean charge—The arithmetic mean of the transferred charges corresponding to a given capacitor voltage, as determined from a specified alternating-charge characteristic curve.

mean charge characteristic—The function giving the relation of mean charge to capacitor voltage.

meander line—A transmission-line-matching section whose electrical length is dependent on frequency. The characteristics of a meander line are determined primarily by the width of the structure, the spacing between adjacent turns, and the angle of the line with respect to the ground plane. If the turns have sufficient separation that there is no space coupling between adjacent turns, the meander line becomes a simple length of transmission line.

mean free path—1. The average distance that sound waves travel between successive reflections in an enclosure. 2. The average distance between collisions of atomic particles, which may be further specified according to type of collision (e.g., elastic, inelastic).

mean life—Also called average life. 1. In a semiconductor, the time taken by injected excess carriers to recombine with others of the opposite sign. 2. A measure of the probability that a part or equipment will function satisfactorily during its constant-failure-rate period. It is unrelated to longevity.

mean power of a radio transmitter—Power supplied to the antenna transmission line by a transmitter during normal operation, averaged over a time sufficiently long compared with the period of the lowest frequency encountered in the modulation. A time of 0.1 second during which the mean power is greatest will be selected normally.

mean pulse time—The arithmetic mean of the leading-edge and trailing-edge pulse times.

means of communications—The medium (i.e., electromagnetic or sound waves, visual messenger) by

which a message is conveyed from one person or place to another.

mean time between failures—Abbreviated MTBF. 1. The average length of time between successive system failures. It is the reciprocal of the sum of the failure rates of all components and connections in the system. 2. The average time between failures of a continuously operating device, circuit, or system. 3. For a particular interval, the total functioning life of a population of an item divided by the total number of failures within the population during the measurement involved.

mean time between maintenance—Abbreviated MTBM. The mean of the distribution of the time intervals between maintenance actions (preventive, corrective, or both).

mean time to failure—Abbreviated MTTF. In a piece of equipment, its measured operating time divided by its total number of failures during that time. Normally this measurement is made between the early-life and wearout failures.

mean time to first failure—Abbreviated MTTFF. A special case of MTBF, where T is the accumulated operating time to first failure of a number of devices (failures).

mean time to repair—Abbreviated MTTR. 1. The total effective maintenance time during a given time interval divided by the total number of failures during the interval. 2. The arithmetic average of time required to complete a repair activity. 3. The total corrective maintenance time divided by the total number of corrective maintenance actions during a given period.

measurand—Also called stimulus. The physical quantity, force, property, or condition measured by an instrument.

measured pickup—The value of current or voltage at or below which the contacts of a relay must assume their fully operated position.

measured service—A type of telephone service for which a charge is made in accordance with the number of calls or message units during the billing period.

measurement—1. The determination of the existence or magnitude of a variable. Measuring instruments include all devices used directly or indirectly for this purpose. 2. The act of determining the magnitude of something, in terms of a recognized standard.

measurement component—Those parts or sub-assemblies used primarily for the construction of measurement apparatus, excluding screws, nuts, insulated wire, or other stable materials.

measurement device—An assembly of one or more basic elements with other components needed to form a self-contained unit for performing one or more measurement operations. Included are the protecting, supporting, and connecting as well as functioning parts.

measurement energy—The energy required to operate a measurement device or system. Normally it is obtained from the measurand or the primary detector.

measurement equipment—Any assemblage of measurement components, devices, apparatus, or systems.

measurement inverter—See measuring modulator.

measurement range of an instrument—That part of the total range of measurement through which the accuracy requirements are to be met.

measurement voltage divider—Also called voltage ratio or volt box. A combination of two or more resistors, capacitors, or other elements arranged in series so that the voltage across any one is a definite, known fraction of the voltage applied to the combination (provided the current drain at the tap point is negligible or taken into account). The term *volt box* is usually limited

to resistance voltage dividers intended for extending the range of direct-current potentiometers.

measuring modulator—Also called measurement inverter or chopper. An intermediate means of modulating a direct-current or low-frequency alternating-current input in a measurement system to give a proportionate alternating-current output, usually as a preliminary to amplification.

mechanical bail—Switch action in which, upon actuation of one station, the switch changes the contact position, mechanically locks the switch in that position, and releases any station previously actuated.

mechanical bandspread—A vernier tuning dial or other mechanical means of lengthening the rotation of a control knob. This permits more precise tuning in crowded shortwave bands.

mechanical bias—A mechanical force tending to move the armature of a relay toward a given position.

mechanical compliance—The displacement of a mechanical element per unit of force, expressed in centimeters per dyne. It is the reciprocal of stiffness and is analogous to capacitance.

mechanical coupling—*See* acoustic coupling.

mechanical differential analyzer—A form of analog computer in which interconnected mechanical surfaces are used for solving differential equations.

mechanical drum programmer—A sequencer that operates switches by means of pins placed on a rotating drum. The switch sequence may be altered by changing the pin pattern.

mechanical filter—1. *See* mechanical wave filter. 2. Mechanical resonators coupled by mechanical means. Piezoelectric or magnetostrictive transducers are used to convert electrical and mechanical energy at input and output. Resonators are bars, discs, or electrode pairs; coupling elements are rods, wires, or nonelectroded regions. *See* monolithic filter.

mechanical impedance—The complex ratio of the effective force acting on a specified area of an acoustic medium or mechanical device to the resulting effective linear velocity through or of that area, respectively. The unit is newton-s/m or the mks mechanical ohm. (In the cgs system, the unit is the dyne-s/cm or the mechanical ohm.)

mechanical joint—A joint made by clamping cables or other conductors together mechanically rather than by soldering them.

mechanical life—The maximum number of complete cycles through which a device may be actuated without electrical or mechanical failure.

mechanically timed relay—A relay that is mechanically timed by such means as a clockwork, escapement, bellows, or dash-pot.

mechanically tuned oscillator—Any oscillator that is specifically designed for frequency tuning by mechanical means. Typically a cavity or discrete element.

mechanical ohm—The magnitude of a mechanical resistance, reactance, or impedance for which a force of 1 dyne produces a linear velocity of 1 centimeter per second (dyn-s/cm). When expressed in newton-seconds per meter it is called the mks mechanical ohm.

mechanical overtravel—The shaft travel of a precision potentiometer between each end point (or limit of theoretical electrical travel) and its adjacent corresponding limit of total mechanical travel.

mechanical phonograph—A phonograph whose playback stylus drives the diaphragm of an acoustic pickup that radiates acoustic energy without any further amplification.

mechanical phonograph recorder—Also called mechanical recorder. Equipment that converts electric

or acoustic signals into mechanical motion and cuts or embosses it into a medium.

mechanical reactance—The magnitude (size) of the imaginary component of mechanical impedance.

mechanical reader—A reader that senses characters on a perforated tape by means of a contact closure caused by each hole.

mechanical recorder—*See* mechanical phonograph recorder.

mechanical recording head—*See* cutter.

mechanical rectifier—A rectifier in which its action is done mechanically (e.g., by making and breaking the electrical circuit at the correct times with a rotating wheel or vibrating reed).

mechanical register—An electromechanical device that records or indicates a count.

mechanical reproducer—*See* phonograph pickup.

mechanical resistance—The real part of the mechanical impedance. The cgs unit is the mechanical ohm. The mks unit is the mks mechanical ohm.

mechanical scanning—An obsolete type of scanning in which a rotating device, such as a disc or mirror, breaks up a scene into a rapid succession of narrow lines for conversion into electrical impulses.

mechanical shock—Shock that occurs when the position of a system is significantly changed in a relatively short time in a nonperiodic manner. It is characterized by suddenness and large displacements which develop significant internal displacements within the system.

mechanical switch—1. Bringing together or separating the surfaces of two or more metallic contacts. Mechanical switches are operated manually or electromagnetically, as in relays. 2. A switch in which the contacts are opened and closed by means of a depressible plunger or button.

mechanical television system—A television system that uses mechanical scanning.

mechanical tilt—1. Tilt of the mechanical axis of an antenna. 2. The angle of this tilt is shown by the tilt indicator dial.

mechanical timer—A timer that does not require electrical power to run or reset. Usually spring wound.

mechanical transducer—A device that transforms mechanical energy directly into acoustical energy.

mechanical transmission system—An assembly of gears, etc., for transmitting mechanical power.

mechanical tuning range—The frequency range of oscillation of a klystron that is obtainable by tuning mechanically while keeping the reflector voltage optimized for the peak of the reflector-voltage mode.

mechanical tuning rate—In a klystron, the frequency change per degree of rotation of the tuning apparatus while oscillation is maintained on the peak of the reflector-voltage mode.

mechanical wave filter—Also called mechanical filter. A filter that separates mechanical waves of different frequencies.

mechanical waveform synthesizer—A device that mechanically generates an electrical signal with the desired waveform.

mechanism of failure—*See* failure mode, 1.

mechanized assembly—The joining together of elements by operators using semiautomatic equipment as contrasted to fully automatic assembly.

media—Communications channels over which LANs operate. These include coaxial cable, twisted-pair telephone wiring, and fiber optic cabling.

median—1. The middle, or average, value in a series (e.g., in the series 1, 2, 3, 4, and 5, the median is 3). 2. The middle value in a set of measured values when the items

are arranged in order of magnitude. If there is no middle value, the median is the average of the two middle values. *Compare* mode and mean.

medical amplifier—Amplifier designed for receiving medical and biological signals (EEG, ECG, etc.) and increasing their magnitude.

medical diathermy—The production of heat in body tissues for therapeutic purposes by high-frequency currents that are insufficiently intense to damage tissues or to impair their vitality. Diathermy has been used in treating chronic arthritis, bursitis, fractures, gynecologic diseases, sinusitis, and other conditions.

medical electronics—1. The branch of electronics concerned with its therapeutic or diagnostic applications in the field of medicine. 2. The application of the tools, techniques, and methods of electronic technology to the problems of medicine.

medical sonic applicator—An electromechanical transducer designed for the local application of sound for therapeutic purposes, for example, in the treatment of muscular ailments.

medium—Anything used for the propagation or transmission of signals, usually in the form of electrons or modulated radio, light, or acoustic waves; examples include optical fiber, cable, wire, dielectric slab, water, air, or free space.

medium error—Semiconductor memory condition in which the cell or cells will properly store data under some conditions or operations (voltage, temperature, and pattern) but will make errors under other conditions of operation.

medium frequency—The band of frequencies between 300 kHz and 3 MHz (100 to 1000 meters).

medium-power silicon rectifiers—Rectifiers with maximum continuous rating of 1 to 50 average amperes per section in a single-phase, half-wave circuit.

medium-scale integration—Abbreviated MSI. 1. Integrated circuits that function as simple, self-contained logic systems, such as decade counters or 5-bit shift registers. Such chips may contain up to 100 gates. 2. The accumulation of several circuits (usually less than 100) on a single chip of semiconductor. 3. The physical realization of a microelectronic circuit fabricated from a single semiconductor integrated circuit having circuitry equivalent to more than 10 individual gates or active circuit functions. 4. The technology that produces microcircuits with 15 or more active devices on a single chip. Most op amps are MSI devices. 5. A classification of ICs by size, applicable to chips containing between 12 and 100 gates or circuits of equivalent complexity. 6. A class of integrated circuits having a density between those of large-scale integration and small-scale integration.

medium speed data rate—Data transmission at a rate between 151 and 2400 bauds.

medium wave—The band of frequencies found on a regular AM radio dial, 540 to 1600 kHz.

meg—Abbreviation for megohm.

mega-—Prefix denoting 10^6 (one million). Letter symbol: M.

megabar—The absolute unit of pressure; equal to one million bars.

megabit—Abbreviated Mb or Mbit. 1,000,000 bits or, exactly, 1,048,576 bits; used in describing data transfer rates as a function of time (Mbps). *See* bit.

megabyte—Abbreviated Mbyte, MB, Meg, or M. 1,048,576 bytes, equal to 1024 kilobytes or 8,388,608 bits; basic unit of measurement of mass storage. *See* byte.

megacycle—One million cycles—obsolete term replaced by megahertz (MHz).

megaflop—Abbreviated Mflops. One million floating-point operations per second.

megaflops per second—Millions of floating-point operations per second; a measure of a computer's processing capability.

megahertz—One million hertz. Letter symbol: MHz.

megampere—One million amperes. Letter symbol: MA.

megarad—A unit for measuring radiation dosage. Equal to one million or 10^6 rads.

megatron—A tube having a high power output at high frequencies, but very low interelectrode capacitances because its electrodes are arranged in parallel layers. *See also* disc-seal tube.

megavolt—One million volts. Letter symbol: MV.

megavoltampere—One million voltamperes. Letter symbol: MVA.

megawatt—Abbreviated MW. One million watts.

megawatthour—One million watt-hours. Letter symbol: MWh.

Megger—A high-range ohmmeter having a built-in hand-driven generator as a direct voltage source, used for measuring insulation resistance values and other high resistances. Also used for continuity, ground, and short-circuit testing in general electrical power work.

megohm—Abbreviated meg. One million ohms.

megohm-farads—*See* megohm-microfarad.

megohm-microfarad—A term used to indicate the insulation resistance of capacitors. It is equal to the product of the insulation resistance in megohms and the capacitance in microfarads. For larger high-voltage capacitors, megohm-farads are used.

megohm sensitivity—The resistance in megohms that must be placed in series with a galvanometer in order that an applied emf of 1 volt shall produce the standard deflection. If the resistance of the galvanometer coil itself is neglected, the number representing the megohm sensitivity is equal to the reciprocal of the number representing the current sensitivity.

Meissner effect—The sudden loss of magnetism in superconductors as they are cooled below the temperature required for superconductivity. As a result, they become diamagnetic—i.e., the self-induced magnetization opposes the applied magnetic field to such an extent that there is no longer a magnetic field.

Meissner oscillator—An oscillator in which the grid and plate circuits are inductively coupled through an independent tank circuit, which determines the frequency.

mel—A unit of pitch. A simple 1000-hertz tone, 40 dB above a listener's threshold, produces a pitch of 1000 mels. The pitch of any sound that is judged by the listener to be n times that of a 1-mel tone is n mels.

melodeon—A broadband, panoramic countermeasures receiver. It displays all types of received electromagnetic radiation as vertical pips on a frequency-calibrated CRT indicator.

melt—Molten semiconductor material from which are drawn the basic single-crystal ingots.

melback process—The making of junctions by melting a correctly doped semiconductor and allowing it to refreeze.

melback transistor—A grown transistor produced by melting the tip of a double-doped pellet. Junctions are formed when the tip recrystallizes.

melting channel—The restricted portion of the charge in a submerged horizontal ring-induction furnace. The induced currents are concentrated here to effect high energy absorption and thereby melt the charge.

melting current—The minimum current that causes a fuse to melt before the end of a given period.

melt-quench transistor—A junction transistor made by quickly cooling a meltback region.

membrane potential—The electric potential that exists across the two sides of a membrane.

membrane switch—1. A thin, flat, lightweight panel containing one or more individual touch-activated switches. An upper membrane with a flexible, conductive material on the lower side is separated by a shimlike spacer from a lower substrate that contains one or more sets of switch contact points. Depressing the membrane touches the conductive surfaces on the lower side of the membrane to the contact points to close the circuit. When the switch is released, the flexible membrane returns to its original position and breaks contact. 2. Contacts and interconnections deposited on two outside layers separated by a third layer that acts as a spacer and maintains the contact gap. A decorative graphic overlay is generally secured to the top layer of the switch with adhesive. The flexible top layer acts as a key cap. The bottom layer can be made of the same flexible material, or it can be a rigid printed circuit board that provides mechanical support. 3. A sandwich of three polyester films. The front layer is the membrane, with a moving contact on its inner surface. Stationary contacts are on the front surface of the rear layer or base. The middle layer contains openings that expose the moving contacts to the stationary ones. Pushing the front sheet over a cut-out area flexes the membrane toward the rear layer, closing the contacts. Only a few thousandths of an inch movement and a few ounces of pressure are required to make contact.

Membrane switch.

memistor—A nonmagnetic memory device composed of a resistive substrate in an electrolyte. When the device is used in an adaptive system, a dc signal deposits copper from an anode on the substrate, thus reducing the resistance of the substrate. Reversing the current reverses the process, increasing the resistance of the substrate.

memory—1. The equipment and media used to hold machine-language information in electrical or magnetic form. Usually, the word *memory* means storage within a control system, whereas *storage* is used to refer to magnetic drums, MOS devices, disks, cores, tapes, punched cards, etc., external to the control system. Either term means collecting and holding pertinent information until it is needed by the computer. 2. The tendency of a material to return to its original shape after having been deformed. 3. Any device or circuit capable of storing a digital word or words. 4. The component of a computer, control system, guidance system, instrumented satellite, or the like designed to provide ready access to data or instructions previously recorded so as to make them bear upon an immediate problem. 5. That part of a computer that holds data and instructions. Each instruction or datum

is assigned a unique address that is used by the CPU when fetching or storing the information. 6. The storage capability or location in a computer system that receives and holds information for later use. Also, the storage arrangement, such as RAM or other type.

Memory types.

memory addressing modes—The method of specifying the memory location and an operand. Common addressing modes are direct, immediate, relative, indexed, and indirect. (These modes are important factors in program efficiency.)

memory address register—1. The CPU register in a computer, which holds the address of the memory location being accessed. 2. A multiple-bit register that keeps track of where instructions are stored in the main memory.

memory allocation—In a computer, a technique of allocating memory to processes or devices.

memory array—In a computer, the memory cells arranged in a rectangular geometric pattern on a chip and organized in rows and columns.

memory buffer register—In a computer, a register in which a word is stored as it comes from memory (reading) or just prior to its entering memory (writing).

memory bus—A dedicated bus through which a central processing unit accesses the memory of a computer system.

memory capacity—See storage capacity.

memory cell—A single storage element of a memory, together with the associated circuits for inserting and removing one bit of information.

memory circuit—A circuit that, having been placed in a particular state by an input signal, will remain in that state after the removal of the input signal.

memory counter—Also called rewind. A system that allows recording tape to be rewound automatically to any predetermined point on the tape.

memory cycle—1. In a computer, an operation consisting of reading from and writing into memory. 2. The operations required for addressing, reading, writing, and/or reading and writing data in memory.

memory dump—1. In a computer, a process of writing the contents of memory consecutively in such a form that it can be examined for computer or program errors. 2. A computer printout showing the contents of memory.

memory expansion—Expansion of the horizontal and/or vertical memory contents in a digital scope for easy viewing of critical parts of a stored waveform. Typically, front-panel scope controls provide expansion over a $1 \times$ to $10 \times$ range.

memory fill—In a computer, the placing of a pattern of characters in the memory registers not in use in a particular problem to stop the computer if the program, through error, seeks instructions taken from forbidden registers.

memory hierarchy—A set of computer memories with differing sizes and speeds and usually having different cost-performance ratios. A hierarchy might consist of a very high-speed, small semiconductor memory, a medium-speed core memory, and a large, slow-speed core.

memory integrated circuit—In a computer, an integrated circuit consisting of memory cells and usually including associated circuits such as those for address selection and amplification. A class of ICs that store digital information being expressed in binary numbers. Examples of memory ICs are ROMs, dynamic and static RAMs, EPROMs, and EEPROMs.

memory light—In a calculator, indicates there is a number in the memory.

memory map—A listing of addresses or symbolic representations of addresses that defines the boundaries of the memory address space occupied by a program or a series of programs. Memory maps can be produced by a high-level language such as FORTRAN.

memory-mapped I/O—Operations performed by reading and writing to memory locations dedicated to a device.

memory module—A processor module consisting of memory storage and capable of storing a finite number of words (e.g., 4096 words in a 4 K memory module). Storage capacity is usually rounded off and abbreviated, with K representing each 1024 words.

memory + and - keys—In a computer, direct access to the memory for storing numbers. On machines without these, the memory has to be addressed first and the working register + and - keys used to store a number in the memory.

memory protection—1. The mechanism used to prevent accidental writing into a computer memory location or area. 2. A method of ensuring that the contents of main memory within certain variable limits are not altered or inadvertently destroyed. See storage protection.

memory register—Also called high-speed bus, distributor, or exchange register. 1. In some computers, a register used in all data and instruction transfers between the memory, the arithmetic unit, and the control register. 2. A register in a calculator in which the contents can be added to or subtracted from without being recalled, or which can be recalled for other operations. The contents are available for repeated recall until the register is cleared.

memory relay—A relay in which each of two or more coils may operate independent sets of contacts, and another set of contacts remains in a position determined by the coil last energized. The term is sometimes erroneously used for polarized relay.

memory timer—A timing device wherein the cycle duration is infinitely variable within the specified overall cycle time and having the ability, once the cycle is selected, to repeat this cycle any number of times by a simple mechanical actuation of the time shaft.

memory typewriter—A typewriter that is capable of storing keyboarded material and playing it back automatically. Memory typewriters generally also have some text input features.

memory unit—That part of a digital computer in which information is stored in machine language, using electrical or magnetic techniques.

meniscus lens—A thin lens with one convex and one concave surface. The surface with the greatest radius of curvature is the convex surface for a positive lens and the concave one for a negative lens.

menu—1. The list of available software functions available to the user of a computer software program, displayed on the computer screen and chosen by moving the cursor or entering an appropriate command. 2. A list of options or functions that is displayed on a CRT. The items in the menu are composed of light buttons for light-pen selection and/or of character strings that are alphanumeric key and/or function key selectable. 3. A display on a terminal device that lists options a user may choose. 4. Input device consisting of command squares on a digitizing surface. It eliminates the need for keyboard input for common commands. 5. A list of all the computer programs that can be used (within a package) or a list of all the tasks that can be performed by a program. The menu is displayed on the screen, and a letter or number represents each option. The option is selected by pressing the appropriate key.

mercuric-oxide-cadmium cell—A primary-cell electrochemical system. Its primary advantage is its long shelf life in the fully charged condition and its operation at low temperatures, far below 0°C . Nominal cell voltage is about 0.9 volt.

mercury—A silver-white metal that becomes a liquid above -38.87°C . In addition to thermometers, it is used in switches and many electronic tubes. When it is vaporized, mercury ionizes readily and conducts electricity.

mercury arc—A cold-cathode arc through ionized mercury vapor. A very bright bluish-green glow is given off.

mercury-arc converter—A frequency converter using a mercury-vapor tube.

mercury-arc rectifier—Also called mercury-vapor or simply mercury rectifier. A diode rectifier tube containing mercury vapor. The mercury vapor is ionized by the voltage across the tube, and a much greater current can flow. There is only a small voltage drop in the tube during conduction.

mercury barometer—An instrument for measuring atmospheric pressure.

mercury battery—A type of battery characterized by extremely uniform output throughout its life. Employs a zinc-powder anode; the cathode is mercuric oxide powder and graphite powder.

mercury cell—1. A primary cell with a zinc anode and a mercuric oxide cathode in a potassium hydroxide

Mercury cell.

electrolyte. This cell offers a higher capacity than the alkaline or zinc-carbon cells and a much flatter voltage-discharge characteristic. 2. A small dry cell that provides a constant voltage of 1.35 volts. Used in hearing aids, watches, and calculators.

mercury-contact relay—A relay in which the contacts are mercury.

mercury delay line—*See* mercury memory.

mercury displacement relay—A relay in which the displacement of mercury, such as caused by a solenoid-actuated plunger, results in a mercury-to-mercury electrical contact.

mercury fence alarm—A type of mercury switch that is sensitive to the vibration caused by an intruder climbing on a fence.

mercury-hydrogen spark-gap converter—A spark-gap generator in which the source of radio-frequency power is the oscillatory discharge of a capacitor through an inductor and a spark gap. The latter comprises a solid electrode and a pool of mercury in hydrogen.

mercury-jet scanning switch—A commutating switch in which a stream of mercury performs the switching between the common circuit and those to be sampled. (Not in common use).

Mercury-jet scanning switch.

mercury lamp—An electric discharge lamp in which the major portion of the radiation is produced by the excitation of mercury atoms.

mercury memory—Also called mercury storage and mercury delay line. Delay lines using mercury as the medium for storage of a circulating train of waves or pulses.

mercury motor meter—A motor meter in which a portion of the rotor is immersed in mercury, which directs the current through conducting portions of the rotor.

mercury-pool cathode—The cathode of a gas tube consisting of a pool of mercury. An arc spot on the pool emits electrons.

mercury rectifier—*See* mercury-arc rectifier.

mercury relay—A relay in which the energized coil pulls a magnetic plunger into a tube containing mercury. The plunger moves the mercury in order to make connection between the contacts.

mercury storage—*See* mercury memory.

mercury switch—1. An electric switch comprising a large globule of mercury in a metal or glass tube. Tilting the tube causes the mercury to move toward or away from the electrodes to make or break the circuit. 2. A switch operated by tilting or vibrating that causes an enclosed pool of mercury to move, making or breaking physical and electrical contact with conductors. It is used on tilting doors and windows and on fences.

mercury tank—In a computer, a container of mercury holding one or more delay lines for storing information.

mercury-vapor lamp—A glow lamp in which mercury vapor is ionized by the electric current, producing a bluish-green luminous discharge.

mercury-vapor rectifier—*See* mercury-arc rectifier.

mercury-vapor tube—A tube containing mercury vapor, which when ionized allows conduction and produces a luminous glow.

mercury-wetted contact relay—A special form of reed relay. It consists of a glass-encapsulated reed with its base mounted in a pool of mercury and the other end arranged so as to move between two sets of stationary contacts. By capillary action, the mercury flows up the reed to coat the movable and stationary contact surfaces, thus assuring mercury-to-mercury contact during make.

merge—1. To produce a single sequence of items ordered according to some rule (i.e., arranged in some orderly sequence) from two or more sequences previously ordered according to the same rule, without changing the size, structure, or total number of the items. 2. To combine two or more files of data into one file in a predetermined sequence. 3. To combine two files into one while keeping the original order. 4. Also called a mail merge. Incorporating two individual documents to create a third.

merged technology switch—A means to interconnect two or more circuits using a series of analog and digital switching stages.

merging—Action of combining two computer files into a simple, ordered one.

meridial rays—The rays of light that propagate by passing through the axis of the fiber and that travel in one plane.

mesa—In certain transistors, the raised area (somewhat resembling a geological mesa) left when semiconductor material is etched away to allow access to the base and collector regions.

mesa diffusion—Technique used to manufacture semiconductors having diffused pn junctions. A single base region is diffused over the entire wafer, and an acid is used to etch a mesa configuration for the transistor elements.

mesa isolation—A process for isolating ICs in which transistors, resistors, and other components are fabricated before isolation.

mesa structure—A semiconductor whose structure is moundlike. During processing, material is etched away from the original chip in order to produce the final shape.

mesa transistor—A transistor that is produced by chemically etching away a transistor chip formed by either a double-diffused or diffused-alloy process. When the etching process is complete, the base and emitter regions appear as plateaus above the collector region. One result of the mesa construction is a reduction in the collector-base capacitance as a result of lowering the junction area.

MESFET—Abbreviation for metal epitaxial semiconductor field-effect transistor. A type of FET in which the channel is formed directly beneath a metal gate, which itself is in intimate contact with the semiconductor. Compare with MOSFET, in which the gate is separated from the semiconductor by a thin insulating oxide layer. *See also* gallium arsenide field-effect transistor.

mesh—Sometimes called a loop. A set of branches forming a closed path in a network—provided that if any branch is omitted, the remaining branches do not form a closed path.

mesh beat—*See* moiré, 1.

mesh current—The current assumed to exist over all cross sections of a closed path in a network. It may be the total current in a branch included in the path, or a partial current that, when combined with the others, forms the total current.

message—1. An ordered selection of an agreed set of symbols for the purpose of communicating information. 2. The original modulating wave in a communication system. 3. An arbitrary amount of information whose beginning and end are defined or implied. 4. One or more blocks of data that contain the total information to be transmitted. 5. A group of characters that have a meaning when taken together and that always are handled as a group.

message center—Communication agency charged with the responsibility for acceptance, preparation for transmission, receipt, and delivery of messages.

message circuit—A long-distance telephone circuit used in providing regular long-distance or toll service to the general public, as opposed to a circuit used for private-line service.

message exchange—A service used between a communications line and a computer to perform certain communications functions and free the computer for other tasks.

message interpolation—Insertion of data between syllables or during speech pauses on a busy voice channel without noticeably affecting the voice transmission.

message precedence—Designations employed to indicate the relative order in which a message of one precedence designation is handled with respect to all other precedence designations.

message switching—1. The technique of data transmission in which data may be received, stored until the proper line is available, then retransmitted. No direct connection is set up between the originator of the data and its destination. 2. Routing messages between three or more locations by store-and-forward techniques in a computer.

message unit—1. A unit of measurement used in charging for local telephone messages, based on time and distance between the parties. 2. Call measurement for a call within a local service area for which charges are accrued.

message-waiting lamp—A small lamp on a telephone set that can be lighted (or flashed) from the switchboard (or call waiting panel) to notify a hotel or motel guest that a message is being held for him or her.

metadyne—British term for amplidyne. A direct-current machine used for voltage regulation or transformation. It has more than two brushes for each pair of holes.

metal—A material that has high electrical and thermal conductivity at normal temperatures.

metal-base transistor—A transistor with a base of a thin metal film sandwiched between two n-type semiconductors, with the emitter doped more heavily than the base to give it a high electron-current-to-hole-current ratio.

metal detector—Also called metal locator. An electronic device for detecting concealed metal objects.

metal-etched mask—A mask formed by chemically etching openings in a metal film or plate where it is not protected by photoresist or other chemically resistant material.

metal film resistor—An electronic component in which the resistive element is an extremely thin layer of metal alloy vacuum-deposited on a substrate.

metal foil capacitor—A capacitor in which the electrodes consist of metal foils separated by a dielectric consisting of plastic film or paper.

Metal film resistor.

metal gate—Refers to the use of aluminum as the gate conductor instead of silicon or refractory metals.

metal halide lamp—A discharge lamp in which the light is produced by the radiation from a mixture of metallic vapor (for example, mercury) and the products of the disassociation of halides (for example, halides of thallium, indium, or sodium).

metal-insulator silicon—See MIS.

metallic circuit—A circuit in which the earth itself is not used as ground.

metallic insulator—A shorted quarter-wave section of transmission line, which acts as an electrical insulator at the transmitted frequency.

metallic noise—Weighted noise current in a metallic circuit at a given point when the circuit is terminated at that point in the nominal characteristic impedance of the circuit.

metallic rectifier—A rectifier in which the asymmetrical junction between dissimilar solid conductors presents a high resistance to current flow in one direction and a low resistance in the opposite direction.

metallic rectifier cell—An elementary rectifying device having only one positive electrode, negative electrode, and rectifying junction.

metallic-rectifier stack—A single structure made up of one or more metallic rectifier cells.

metallization—1. The deposition of a thin-film pattern of conductive material onto a substrate to provide interconnection of electronic components or to provide conductive contacts (pads) for interconnections. 2. A film pattern (single or multilayer) of conductive material deposited on a substrate to interconnect electronic components, or the metal film on the bonding area of a substrate that becomes a part of the bond and performs both electrical and mechanical functions. 3. The selective deposition of metal film on a substrate to form conductive interconnection between IC elements and points for connections with the outside world.

metallized capacitor—A capacitor that is made with dielectric film that has had metal vacuum-deposited on it. This thin metallization restricts the maximum current capacity, but at the same time provides a very high volumetric efficiency and a unique self-healing property. Any internal arcover (which could be triggered by a transient voltage spike) will usually clear itself by vaporizing the deposited metal film in the immediate area, thus extending the arc path beyond the sustaining gap length limit. Foil capacitors cannot clear in this manner and may therefore sustain the arcovers and short out.

metallized resistor—A fixed resistor in which the resistance element is a thin film of metal deposited on the surface of a glass or ceramic substrate.

metallizing—Applying a thin coating of metal to a nonmetallic surface. This may be done by chemical

Metal-nitride-oxide semiconductor (MNOS).

deposition or by exposing the surface to vaporized metal in a vacuum chamber.

metal locator — See metal detector.

metal mask (screens) — A screen made not from wire or nylon thread but from a solid sheet of metal in which holes have been etched in the desired circuit pattern. Useful for precision and/or fine printing and for solder cream printing.

metal master — See original master.

metal negative — See original master.

metal-nitride-oxide semiconductor — Abbreviated MNOS. An MOS structure with a layer of silicon nitride added between the metal gate contact and the oxide protective layer to offset the permeability of silicon dioxide by contaminating sodium ions. In suitably fabricated devices, it is possible to generate a relatively nonvolatile memory element by charge storage at the nitride-oxide interface.

metal-on-glass mask — An optical mask comprising a glass substrate selectively covered by a thin opaque metal layer; a type of photomask.

metal-oxide resistor — A type of film resistor in which the material deposited on the substrate is tin oxide, which provides good stability.

metal-oxide semiconductor — Abbreviated MOS.

1. A field-effect transistor in which the gate electrode is isolated from the channel by an oxide film. 2. A capacitor in which semiconductor material forms one plate, aluminum forms the other plate, and an oxide forms the dielectric. 3. A circuit in which the active region is a metal-oxide semiconductor sandwich. The oxide acts as the dielectric insulator between the metal and the semiconductor. 4. A process that results in a structure of metal over silicon oxide over silicon. By appropriate topology this generates field-effect transistors, capacitors, or resistors. 5. Referring to a field-effect transistor (MOSFET) that has a metal gate insulated by an oxide layer from the semiconductor channel. A MOSFET is either enhancement-type (normally turned off) or depletion-type (normally turned on). MOS also refers to integrated circuits that use MOSFETs (virtually all enhancement-type). 6. Technology that employs field-effect transistors having a metal or conductive electrode that is insulated from the semiconductor material by an oxide layer of the substrate material. Whereas, bipolar devices permit current in only one direction, MOS devices permit bidirectional current. 7. A metal over silicon oxide over silicon arrangement that produces circuit components such as transistors. Electrical characteristics are similar to vacuum tubes. 8. A transistor whose characteristics are high packing density, low power dissipation, slow speed, and high input resistance.

metal-oxide semiconductor field-effect transistor — Abbreviated MOSFET. 1. A device consisting of diffused source and drain regions on either side of a p or n channel region, and a gate electrode insulated from the channel by silicon oxide. When a control voltage is applied to the gate, the channel is converted to the same type of semiconductor as the source and drain. This eliminates part of the pn junction and permits current to be established between the source and drain. Functionally, the main difference between a MOSFET and a bipolar transistor is that the source and drain of the MOSFET are interchangeable, unlike the emitter and collector of the bipolar transistor. 2. An insulated-gate field-effect transistor in which the insulating layer between each gate electrode and the channel is oxide material. 3. A class of voltage-driven devices that do not require the large input drive currents of bipolar devices. MOSFETs are a type of field-effect transistor that operates and functions similar to a junction field-effect transistor. The difference is that in the MOS device the controlling gate voltage is applied to the channel region across an oxide insulating material, rather than across a pn junction. The term can be applied either to transistors in an IC or to discrete power devices. The major advantage of a MOSFET is low power requirement due to its insulation from source and drain. Other advantages are its process simplicity, savings in chip real estate, and the ease of interconnection on chip. MOSFETs are of both p-channel and n-channel types.

Metal-oxide semiconductor field-effect transistor.

metal-tank mercury-arc rectifier — A mercury-arc rectifier in which its anodes and mercury cathode are enclosed in a metal chamber.

metal-thick-nitride semiconductor — A device similar to an MTOS device except that a thick layer of silicon nitride or silicon nitride-oxide is used instead of a layer of oxide.

metal-thick-oxide semiconductor—Abbreviated MTOS. A device in which the oxide outside the desired active gate area is made much thicker so that problems with unwanted parasitic devices are reduced.

metal tube—A vacuum tube with a metal envelope. The electrode leads pass through glass beads fused into the metal housing.

metamers—Lights of the same color but of different spectral energy distribution.

meteorological aids service—A radio service in which emissions consist of special signals intended solely for meteorological uses.

meteorological radar station—A station, operating in the meteorological aids service, that employs radar and is not intended for operation while in motion.

meter—*i.* Any measuring device; specifically, any electrical or electronic measuring instrument. *2.* The basic unit of linear measurement in the metric system. Originally based on the distance from the equator to the geographic north pole (10^5 meters). One meter is equal to 39.37 inches, 3.281 feet, or 1.094 yards. Letter symbol: m.

meterampere—A measure of the strength of a radio transmitter. It is equal to the antenna height in meters times the maximum antenna current in amperes.

metercandle—*See lux.*

meter-correction factor—The factor by which a meter reading must be multiplied to compensate for meter errors in order to obtain the true reading.

meter display—A display in which one or more pointer instruments give the indications.

meter-kilogram-second-ampere system of units—*See* mksa electromagnetic system of units.

meter rating—A manufacturer's designation used to indicate the operating limitations of the meter. The full-scale marking on a meter scale does not necessarily correspond to the rating of the meter.

meter resistance—The resistance of a meter as measured at the terminals at a given reference temperature. When applied to rectifier-type meters, the frequency and waveshape of the applied energy, as well as the indicated value at which the measurement is to be made, must be specified.

meter-type relay—A meter movement in which the armature function is performed by a contact-bearing pointer.

metrecon—A storage tube used in scanning converters (e.g., in radar and industrial TV).

metric—A measure for hardware or software performance, or of the extent to which a program exhibits certain characteristics.

metric system—The decimal system of weights and measures, used extensively by scientists.

metric waves—Waves with lengths between 1 and 10 meters (corresponding to frequencies between 300 and 30 MHz, respectively).

MeV—Usually pronounced M-E-V. Letter symbol for million electronvolts. 1 MeV equals 4.45×10^{-20} kilowatthours, or 1.6020×10^{-6} erg.

MEW—Abbreviation for microwave early warning.

MF—*1.* Abbreviation for medium frequency. *2.* Abbreviation for multifrequency.

mf—Alternate abbreviation for microfarad.

mfd—Alternate abbreviation for microfarad.

mH—Letter symbol for millihenry.

MHD—Abbreviation for magnetohydrodynamics.

mho—The unit of conductance of a conductor when a potential difference of 1 volt between its ends maintains an unvarying current of 1 ampere. The mho was the unit

metal-thick-oxide semiconductor — microcircuit

of conductance in the mksa system. This term has now been replaced by siemens.

MHz—Letter symbol for megahertz.

MIC—*1.* Abbreviation for monolithic integrated circuit. *2.* *See* microwave integrated circuit.

mica—*1.* A transparent mineral that can be split into thin sheets. Because of its excellent insulating and heat-resisting qualities, it is used to separate the plates of capacitors and to insulate electrode elements in vacuum tubes. *2.* A silicate that separates into layers and has high insulation resistance, dielectric strength, and heat resistance. It is used as an insulation wrap in wires and cables to a limited degree where radiation resistance requirements are severe and for high-temperature work demanding good heat resistance.

mica capacitor—*1.* A fixed capacitor employing mica sheets as the dielectric material between adjacent plates. The complete units are usually encased in molded Bakelite. *2.* A capacitor with a dielectric consisting of mica.

MICamp—Abbreviation for microwave integrated circuit amplifier

MICR—Abbreviation for magnetic-ink character recognition.

micro—*1.* In the metric system, a prefix meaning one millionth ($1/1,000,000$). *2.* A prefix meaning something very small.

microalloy diffused transistor—Abbreviated MADT. A transistor fabricated by etching emitter and collector pits into heavily doped germanium, depositing epitaxial layers of intrinsic germanium on both sides of the wafer, and adding electrodes that are plated and electroplated in the pits.

microalloy transistor—Abbreviated MAT. A high-frequency transistor in which the emitter and collector are alloyed to a slight depth on opposite sides of the germanium base material by an electrochemical process.

microammeter—A meter having a scale that reads in microamperes, for measuring extremely small currents.

microampere—One millionth of an ampere.

microbar—A unit of pressure commonly used in acoustics. One microbar is equal to one dyne per square centimeter. (Originally the term *bar* denoted dyne per square centimeter. Therefore, to avoid confusion it is preferable to use *microbar* or *dynes per square centimeter* when speaking of sound pressures.)

micro B-display—A B-scope in which range and azimuth data are so expanded that only a small portion of the area under surveillance is presented, and, because of the degree of expansion, distortion of the presentation is negligible.

microbond—The realization of a very small fastened joint between conductors or between a conductor and a microelectronic chip device.

microcassette—A miniature cassette system originated by Olympus, allowing 30 minutes of recording per side on a capstan-driven tape, $1/7$ inch (3.63 mm) wide, running at $1\frac{1}{16}$ ips (2.38 cm/s).

microcircuit—*1.* A small circuit with a high equivalent-circuit-element density, and considered as a single part, composed of interconnected elements on or within a single substrate, that performs an electronic-circuit function. (According to this definition, such structures as printed wiring boards, circuit card assemblies, and modules composed exclusively of discrete electronic parts are not considered to be microcircuits.) *2.* An integrated circuit. *3.* The physical realization of a (hybrid or monolithic) interconnected array of very small active and passive electronic elements. *4.* A term used to describe the miniaturization of solid-state discrete components onto a continuous substrate.

microcircuit module—An assembly of microcircuits or of microcircuits and discrete parts, designed to perform an electronic-circuit function or functions and constructed in such a manner that it is considered to be a single entity for the purposes of specification, testing, commerce, and maintenance.

microcircuit wafer—A microwafer carrying one or more circuit functions such as a flip-flop or gate. Integrated-circuit chips may be bonded to deposited conductors.

microcode—1. A computer-coding system that includes suboperations, such as multiplication and division, that ordinarily are inaccessible in programming. A list of very small program steps. 2. A set of control functions performed by the instruction decoding and execution logic of a computer that defines the instruction repertoire of that computer. Microcode is not generally accessible by the programmer. 3. Sequences of low-level steps, making up machine instructions, that are built into a microprocessor that directly control the interaction of the processor's computing elements—that is, machine instructions wired into the hardware that is being controlled. 4. Permanent basic subcommands, built into a computer, that are executed directly by the computer. Generally, these commands define the instruction set of a microprogrammable computer.

microcoding—In a computer, a system of coding that uses suboperations not ordinarily accessible in programming.

microcomponents—1. Those components smaller than existing components by several orders of magnitude. 2. An assembly of very small, interconnected discrete components—active or passive—that forms an electronic circuit. Interconnection of the various leads is by soldering or welding. Microcomponents use no substrates.

microcomputer—1. A general-purpose computer composed of standard LSI components built around a central processing unit (CPU). The CPU (or microprocessor) is program-controlled, featuring arithmetic and logical instructions and a general-purpose parallel I/O bus. The CPU is generally contained on a single chip. Generally intended for dedicated applications, the microcomputer also includes any number of ROMs and RAMs (for instruction and data storage) and, in some cases, one or more I/O devices. The simplest microcomputer consists of one CPU chip and one ROM. 2. A computer whose major sections—CPU, control, timing, and memory—are each contained on a single integrated-circuit chip, or, at most, a few chips. An LSI computer. 3. A computer that has a single or multichip LSI CPU, as distinguished from a minicomputer. 4. A class of computer having all major central processor functions contained on a single printed circuit board constituting a stand-alone module. 5. A computer whose central processing unit is a microprocessor. A microcomputer includes microprocessor, memory, and input/output controllers. 6. A device consisting of a central processor (usually a microprocessor, but sometimes a custom LSI chip set or a bit-slice processor) combined with a memory and input/output.

microcomputer development system—Abbreviated MDS. Also called expandable breadboarding system. 1. A key tool used in the development phase of microprocessor-based computers. It provides an efficient means of program coding, subprogram testing, and final testing for the completed program in a simulated operating condition without the use of the hardware that is contained in the final end product. The elements of the MDS combine to make up a complete microprocessor-based computer, which is composed of the central processing unit or microprocessor unit; a mass-storage memory section; either a floppy disk or tape cassette, complete

with associated drive and control circuits; a CRT terminal (video readout), a keyboard; and, as there is in most systems, a printer. In addition, an emulator module is part of the system and is used to test the operation of the developed system under defined conditions without the use of final hardware. 2. A system designed exclusively to aid in the development of microprocessor systems. Microcomputer development systems enable a designer to develop software and hardware as if many standard operating system utilities were present in his or her final design. These utilities, however, actually reside in the development system and therefore do not require costly additions to every shipped system. 3. Microcomputer equipped with the hardware and software facilities required for efficient program development and hardware debugging.

microcontroller—A complete microprocessor system on a chip. Includes on-chip the CPU, local RAM, local ROM or EPROM, clock and control circuits, and serial and parallel I/O ports that can be programmed for various control functions. *See also* chip sets.

microcrack—A thin crack in a substrate or chip device, or in thick-film trim-kerf walls, that can only be seen under magnification and which can contribute to latent failure phenomena.

microdensitometer—An instrument used in spectroscopy to measure lines in a spectrum by light transmission measurement.

microelectrode—An extremely small electrode. Some microelectrodes are small enough to contact a single biological cell.

microelectronic circuit—Discrete electrical components assembled and connected in extremely small and compact form.

microelectronic device—An alternate term for integrated circuit.

microelectronics—Also called microsystems electronics. 1. The entire body of electronic art that is connected with or applied to the realization of electronic systems from extremely small electronic parts. 2. *See* integrated circuit. 3. All techniques for the manufacture of extremely small electronic circuits, generally including all types of silicon integrated circuits, thin-film circuits, and thick-film circuits. 4. The physical realization of electronic circuits or systems from a number of extremely small circuit elements inseparably associated on or within a continuous body. Microelectronics has developed along two basic technologies: monolithic integrated circuits and hybrid integrated circuits. 5. The field that deals with techniques for producing miniature circuits, e.g., integrated circuits, thin-film techniques, and solid-state logic modules. 6. The art of electronic equipment design and construction that uses microminiaturization schemes.

microelement—A resistor, capacitor, or transistor, diode, inductor, transformer, or other electronic element or combination of elements mounted on a small ceramic wafer 0.01 inch (or 0.25 mm) thick and about 0.3 inch (0.75 mm) square. Individual microelements are stacked, interconnected, and potted to form micromodules.

microelement wafer—A microwafer carrying one or more components or a simple network. The network can consist, for example, of several thin-film resistors deposited directly on the wafer.

microfarad—One millionth of a farad. Letter symbol: μF .

microfaradmeter—*See* capacitance meter.

microflash—An extremely short electronic flash, having a duration of about 1×10^{-6} second. Used in photographing rapidly moving subjects.

microflash lamp—A lamp that emits radiation pulses having a duration of approximately 1 microsecond.

micrographics—The use of microfilm and microfiche for filing basic documents that must be retained and made available for infrequent use. Special computer software can be used to maintain an index of such documents and to aid in their retrieval.

microgroove—In disc recording, the groove width of most long-play and 45-rpm records. Normally it is 0.001 inch (25.4 μm), or about half as wide as the groove on a 78-rpm record. (No longer manufactured.)

microgroove record—*See* long-play record.

microhenry—One millionth of a henry.

microhm—One millionth of an ohm.

microinstruction—Also called elementary operation, cycle, or function. 1. A very simple instruction (typically a register-to-register copy). 2. A bit pattern that is stored in a microprogram memory word and specifies the operation of the individual LSI computing elements and related subunits, such as main memory and input/output interfaces.

microinstruction sequence—The series of microinstructions that the microprogram control unit (MCU) selects from the microprogram to execute a single macroinstruction or control command. Microinstruction sequences can be shared by several macroinstructions.

microlock—A phase-lock loop system for transmitting and receiving information. Because the system reduces bandwidth drastically, it is used as a radar beacon for tracking, or to provide telemetering data.

micrologic elements—1. A group of high-speed, low-powered integrated logic building blocks primarily intended to be used in building the logic section of a digital computer. 2. Semiconductor networks used in computer and other critical circuits.

micromanipulators—Devices that provide means for accurately moving minuscule tools over and onto the surface of a microscopic object.

micromassage—*See* intercellular massage.

micrometer—One millionth of a meter.

micromho—One millionth of a mho or of a siemens. Replaced by microsiemens.

micromicro—An obsolete prefix meaning one millionth of a millionth, or 10^{-12} . Now called pico-.

micromicrofarad—Obsolete term for 10^{-12} farad. Now called picofarad.

micromicrowatt—Obsolete term for 10^{-12} watt. Now called picowatt.

microminiature lamp—Any incandescent lamp, usually rated in the milliwatt range, that operates on 3 volts or less. Diameters range from 0.01 to 0.06 inch, or 0.25 to 1.5 mm.

microminiaturization—1. The producing of micro-miniature electronic circuits from individual miniature solid-state and other nonthermionic components. 2. A relative degree of miniaturization resulting in an equipment or assembly volume an order of magnitude smaller than that existing in subminiature equipment. 3. The technique of packaging a microminiature part of an assembly composed of elements radically different in shape and form. Electronic parts are replaced by active and passive elements through use of fabrication processes such as screening, vapor-deposition diffusion, and photoetching. 4. The process of packaging an assembly of microminiature active and passive electronic elements, replacing an assembly of much and different parts.

micromodule—1. A tiny ceramic wafer made from semiconductive and insulative materials. It is capable of functioning as either a transistor, resistor, capacitor, or other basic component. 2. A microcircuit constructed of a number of components (e.g., microwafers) and

encapsulated to form a block that is still only a fraction of an inch in any dimension.

micron—1. An absolute unit of length equal to 10^{-6} meter. The term micrometer is now preferred. 2. A unit used in the measurement of very low pressures. It is equivalent to 0.001 mm (10^{-6} meter) of mercury at 32°F or 0°C.

microphone—1. An electroacoustic transducer that responds to sound waves and delivers essentially equivalent electric waves. 2. A device for converting sound waves or sound-producing vibrations (as from the strings of a guitar) into corresponding electrical impulses. Microphones may use as transducing elements crystal or ceramic chips, ribbons, moving coils, or capacitors, and different recording applications may call for different transducers as well as for different directional patterns and impedances.

microphone amplifier—Also called a microphone preamplifier. An audio-frequency amplifier that boosts the output of a microphone before the signal reaches the main audio-frequency amplifier.

microphone boom—A movable crane from which a microphone is suspended.

microphone button—The resistance element of a carbon microphone. It is button-shaped and filled with carbon particles.

microphone cable—A shielded cable for connecting a microphone to an amplifier.

microphone mixer—An audio mixer that feeds the output from two or more microphones into a single input to an audio amplifier. The output from each microphone is adjustable by individual controls on the mixer.

microphone preamplifier—*See* microphone amplifier.

microphone sensitivity—The voltage that is produced by a microphone that is exposed to a specified sound pressure level. Usually specified in dBV in a 94 dB sound pressure level (spl) or 74 dB spl sound field, measured with no load on the microphone.

microphone stand—A stand that holds a microphone the desired distance above the floor or a table.

microphone transformer—An iron-core transformer used for coupling certain microphones to an amplifier or transmission line.

microphonics—1. The generation of an electrical noise signal by mechanical motion of internal parts within a device. 2. Electrical disturbance (noise) due to mechanical disturbances of circuit elements. 3. A form of noise interference arising from the tendency for vibrations of certain objects to be converted into corresponding electrical signals. A microphonic device will cause a “bong” or “bing” in the signal when subjected to jarring. 4. Audio-frequency noise caused by the mechanical vibration of elements within a system or component. 5. Microphone noise that occurs in lasers when vibrations are transferred to the resonator structure.

microphonism—1. The production of noise as a result of mechanical shock or vibration. 2. The quasiperiodic voltage output of a tube produced by mechanical resonance of its elements as a result of mechanical impulse excitation. 3. The periodic voltage output of a tube produced by mechanical resonances of its elements as a result of sustained mechanical excitation. 4. The output voltage of a tube acting as an electrical transducer of mechanical energy.

microphonograph—A device that amplifies and records weak sounds; used in training the deaf to speak.

microphonoscope—A binaural stethoscope using a membrane in the chest piece to accentuate the sound.

microphotograph—A small picture of a large subject. The microfilming of a check or other document produces a microphotograph.

microprobe—An extremely sharp and small exploring tool head attached to a positioning handle. Used for testing microelectronic circuits by establishing ohmic contact.

microprocessor—Also called MPU (microprocessor unit). 1. A central processing unit (CPU) fabricated on one or more chips, containing the basic arithmetic, logic, and control elements of a computer that are required for processing data. 2. An integrated circuit that accepts coded instructions, executes the instructions received, and delivers signals that describe its internal status. The instructions may be entered or stored internally. Widely used as control devices for household appliances, business machines, toys, etc., as well as for microcomputers. 3. An electronic integrated circuit, typically a single-chip package, capable of receiving and executing coded instructions.

microprocessor development system—A combination of hardware and software that acts as a tool for micro system design and debugging from concept to final production release. It contains assembler, compiler, and editor programs to assist with the original program writing. It also can simulate the system, both at the concept stage and during the final integration. The larger memory available makes it practical to document programs, that is, to add remarks within the program that will be ignored by the microprocessor and that will indicate to a subsequent user the purposes of specific instructions. These remarks do not, of course, go into the final ROM. The development system is also able to transfer the debugged program that it is already using into PROM or EROM.

microprocessor emulator—A software routine or device that imitates the functions of a specific microprocessor.

microprogram—1. A computer program written in the most basic instructions or subcommands that can be executed by the computer. Frequently, it is stored in a read-only memory. *See also* firmware. 2. A special-purpose program, stored in a fixed memory, that is initiated by a single instruction in a system's main program. For example, one instruction in the main program may initiate a stored microprogram of six or seven instructions needed to execute the single main program instruction. 3. In a computer, a subelement of a conventional program built up of a sequence of even smaller operations called microinstructions. Each microinstruction is further subdivided into a collection of microoperations carried out in one basic machine cycle. (For example, the computer program consists of a sequence of instructions that are carried out in a specific order. Each instruction consists of a routine of one or more steps. This sequence of computer machine cycles necessary to execute a single instruction is called a microprogram.) 4. A sequence of instructions held in the control store that determines what operations the processor performs for each command given to it by the main memory. 5. A type of program that directly controls the operation of each function element in a microprocessor. 6. Stored routines in CPU control memory that define machine instructions as a series of elemental steps to be executed by the processor's control section. 7. A special computer program that sequences the control unit of a processor. It implements sequential instruction fetch, plus decoding and execution, by providing the appropriate signals to the required gates. Most MPUs are internally microprogrammed and can be microprogrammed by the user. Bit-slices are user microprogrammable. 8. A machine-executable description of

the elementary steps that are executed in the course of what the software sees as an instruction.

microprogrammable computer—A computer in which the internal CPU control sequence for performing instructions is generated from a read-only memory (ROM). By changing the ROM contents, the instruction set can be changed (as contrasted with a fixed-instruction computer).

microprogramming—1. The setting up of basic suboperations for a computer to handle, after which the programmer combines them, and they are presented to the computer again in a higher-level program. For example, if a computer has only basic instructions for addition, subtraction, and multiplication, the instruction for division would be defined by microprogramming. 2. A method of operating the control part of a computer in which each instruction is broken into several small steps (microsteps) that form part of a microprogram. 3. A method of organizing a general-purpose computer to perform desired functions, using instructions stored in a control array.

microprogram store—*See* control store.

microradiometer—Also called a radio micrometer. A thermosensitive detector of radiant power. It consists of a thermopile supported on and connected directly to the moving coil of a galvanometer.

microsecond—One millionth of a second: 1×10^{-6} or 0.000001 second. Letter symbol: μ s.

Microsoft Windows—An operating environment for IBM PCs and compatibles that features icons, pull-down menus, desk accessories, and the ability to easily move text and graphics from one program to another via a clipboard. It can also operate more than one program at a time.

microstrip—Also called stripline. 1. A microwave transmission component in which a single conductor is supported above a ground plane. 2. Printed-wiring LC resonant circuits or transmission lines. Conductive patterns form inductors. Capacitance is developed between the inductive patterns and the ground plane. 3. (Microstripline) A transmission line consisting of a metallized strip and a solid ground plane metallization separated by a thin, solid dielectric. This transmission line configuration permits accurate fabrication of 50-ohm transmission line elements on a ceramic or printed circuit board substrate.

microsyn—A precise and sensitive pickoff device for converting angular displacement within a small range to an electrical signal.

microsystems electronics—*See* microelectronics.

microvolt—One millionth of a volt. Letter symbol: μ V.

microvoltmeter—A highly sensitive voltmeter that measures millionths of a volt.

microvolts per meter—The potential difference in microvolts developed between an antenna system and ground, divided by the distance in meters between the two points.

microvolts/meter/mile—One method of stating the field strength of a radiated field. Radiation from industrial heating equipment, for example, must be suppressed so that the radiated field strength does not exceed 10 microvolts per meter at a distance of 1 mile (1.609 km) from the source.

microwafer—A basic microcircuit building block generally made of beryllia, alumina, or glass. Terminations on the edges are usually of gold on top of chromium, with a heavy nickel overlay for welding.

microwatt—One millionth of a watt. Letter symbol: μ W.

microwave—1. A term applied to waves in the frequency range of 1000 megahertz and upward. Generally defines operations in the region where distributed constant circuits enclosed by conducting boundaries are used instead of the conventional lumped-constant circuit components. 2. An electromagnetic wavelength in (or near) the span of 1–100 cm.

microwave alarm system—An alarm system that employs radio-frequency motion detectors operating in the microwave frequency region of the electromagnetic spectrum.

microwave amplification by stimulated emission of radiation—See maser.

microwave diode—A two-terminal device that is responsive in the microwave region of the electromagnetic spectrum, commonly regarded as extending from 1 to 300 GHz.

microwave discriminator—A tuned cavity that converts a frequency-modulated microwave signal into an audio or video signal.

microwave early warning—Abbreviated MEW. A high-power, long-range, early-warning radar. It has numerous indicators that give high resolutions and large traffic-handling capacity.

microwave filter—A filter built into a microwave transmission line to pass desired frequencies but reject or absorb all other frequencies.

microwave frequency—Any of the ultrahigh frequencies (approximately 1000 MHz and above) suitable for line-of-sight radiocommunication.

microwave holography—The holographic recording of the pattern formed by two sets of coherent microwaves that interfere at a scanning plane. A scanning device converts the microwave interference pattern into a light pattern that is recorded by a suitable camera.

microwave integrated circuit—Abbreviated MIC. 1. An electronic circuit fabricated by microelectronic techniques and capable of operating at frequencies above 1 gigahertz. Either hybrid or monolithic integrated circuit technology may be employed. 2. A hybrid type of construction in which thick- or thin-film technology is used to lay out a pattern of conducting lines on a ceramic substrate, and uncased active devices are then bonded to the conductor pattern. 3. A miniature microwave circuit usually using hybrid circuit technology to form the conductors and attach the chip devices. 4. In the microwave industry, a hybrid using thin- or thick-film conductors and passive components on a ceramic substrate combined with chip-form active and passive components.

microwave intruder detector—A radio-frequency device employing a Doppler frequency shift principle of detection. Microwave energy is generated in a resonant cavity and transmitted into the protection area. Objects within the protected area partially reflect the microwave energy back to the detector. If all objects

within the range are stationary, the reflected waves return at the same frequency; if they strike a moving object, they return at a different frequency. The difference in the transmitted and received frequency appears as a low-frequency signal, which is amplified and used to trip an alarm relay. The shape of the protection area is determined by the shape of the antenna. Range is controlled by adjusting the gain of the amplifier.

microwave level detector—A noncontacting level detector incorporating a microwave transmitter, oscillator, directional antenna, and receiver.

microwave mapping—The pattern of microwave field intensity that can be obtained by detecting the minute expansion of a microwave absorber slab when heated by the microwave field, accompanied by moiré interference of a set of optical fringe patterns on the slab surface pre- and post-deformation.

microwave phototube—A device designed to detect microwave modulation and to mix modulated and unmodulated laser beams. It consists of a photosensitive cathode and a microwave-electron-tube structure that amplifies, detects, and removes the modulation placed on the electron beam by the incident light beam signal.

microwave power transmission—A method of transmitting power through space from a microwave transmitting antenna to a remotely located receiving antenna.

microwave radio relay—The relaying of long-distance telephone calls and television broadcast programs by means of highly directional high-frequency radio waves that are received and sent on from one booster station to another.

microwave refractometer—A device for measuring the refractive index of the atmosphere at microwave frequencies, usually in the 3-cm region.

microwave region—The portion of the electromagnetic spectrum between the far infrared and conventional radio-frequency portion. Commonly regarded as extending from 1000 (30 cm) to 300,000 (1 mm) megahertz.

microwave relay system—A series of ultrahigh-frequency radio transmitters and receivers comprising a system for handling communications (usually multi-channel).

microwave repeater—A repeater station in a microwave radio relay system. Repeaters are spaced 20 to 35 miles (32 to 56 km) apart in a typical microwave system.

microwave routes—Communications pathways in which microwave towers beam signals to and from each other as messages travel to telephones, data terminals, and the like. About 70 percent of interstate telephone messages travel this way.

microwaves—1. Radio frequencies with such short wavelengths that they exhibit some of the properties of light. Their frequency range is from 1000 MHz up.

Microwave frequency chart.

(Microwaves are preferred in point-to-point communications because they are easily concentrated into a beam.)
2. Short electromagnetic waves located between the television transmission and infrared frequency regions. For communication purposes, microwaves offer considerable appeal as they can be focused and directed like light and can be manipulated like electricity, providing a practical means of transmitting information great distances without the use of wires.

microwave spectrum—The spectrum of frequencies suitable for microwave radio communication (300 MHz to 300 GHz).

microwave tube—The source of power for generating microwave frequencies. Primary microwave generating tubes are klystrons, magnetrons, and traveling wave tubes. Other microwave devices include masers, parametric amplifiers, and backward-wave oscillators.

micro-Winchester drive—Also called microdisk drive. A memory storage device for personal computers that uses a 5¼-inch (13.3-cm) metal memory disk.

mid-band—The part of the frequency band that lies between television channels 6 and 7, reserved by the FCC for air, maritime, and land mobile units; FM radio; and aeronautical and maritime navigation. Mid-band frequencies, 108 to 174 MHz, can also be used to provide additional channels on cable television systems.

middle marker—In an instrument landing system, a marker located on a localizer course line, about 3500 feet (1067 m) from the approach end of the runway.

middle-side system—*See* mitte-seite stereo system.

MIDI—Abbreviation for musical instrument digital interface. A standard protocol that allows electronic instruments to communicate with each other and with computers.

midrange—The frequency range between bass and treble, from approximately 500 to 4000 Hz. This most important audio-frequency region includes all the frequencies necessary for intelligibility. Speaker systems often use a midrange unit that typically operates between about 400 and 3000 Hz.

migration—The movement of some metals, notably silver, from one location to another as a result of a plating action that takes place in the presence of moisture and an electrical potential.

mike—Slang for microphone.

MIL—Abbreviation for military. Pertains to a nation's armed forces, including its army, navy, and air force. Specifically, the Armed Forces of the United States.

mil—One thousandth of an inch. Used in the United States for measuring wire diameter and tape thickness.

mileage—Monthly user charges by a telephone company for line mileage based on the class of service the customer has and the air line distance from the base rate area.

military-grade IC—Typically, an integrated circuit whose performance is guaranteed over the temperature range from -55°C to $+125^{\circ}\text{C}$.

military radio station—An amateur radio station licensed to the person in charge of a station at a land location provided for the recreational use of amateur radio operators under military auspices of the Armed Forces of the United States.

military specifications—Documents issued by the Department of Defense that define materials, products, or services used only or predominately by military activities.

military standardization handbooks—Detailed handbooks describing a specific subject that is critical to military design. The title is comprised of the prefix letters MIL-HDBK followed by an assigned serial number. For

example, MIL-HDBK-241 is the design guide for EMI reduction in power supplies.

military standards—Procedures for design, drawing, writing, and testing of components or equipment rather than giving a particular specification.

military temperature range—From -55°C to $+125^{\circ}\text{C}$.

Miller bridge—A type of bridge circuit for measuring the amplification factor of vacuum tubes.

Miller capacitance—Feedback capacitance caused by gate metal overlapping source and drain regions.

Miller effect—The increase in the effective grid-to-cathode capacitance of a vacuum tube because the plate induces a charge electrostatically on the grid through grid-to-plate capacitance.

Miller oscillator—A crystal-controlled oscillator in which the crystal oscillates at its parallel resonant frequency due to the connection of negative resistance across its plates.

milli-—Prefix meaning one thousandth ($1/1000$, or 10^{-3}). 2. One-thousandth part of a whole. Letter symbol: m.

milliammeter—An electric current meter calibrated in milliamperes.

milliampere—One one-thousandth ($.001$) of an ampere. Letter symbol: mA.

millihenry—One one-thousandth ($.001$) of a henry. Letter symbol: mH.

millilambert—A unit of brightness equal to one one-thousandth ($.001$) of a lambert.

millimaxwell—One one-thousandth of a maxwell.

millimeter waves—Electromagnetic radiation in the frequency range of 30 to 500 gigahertz, with corresponding wavelengths of 10 millimeters to 0.6 millimeter.

millimicro-—Obsolete prefix for nano-, representing 10^{-9} .

millimicrometer—A unit of length equal to one ten-millionth of a centimeter (10^{-7} cm), or one one-thousandth of a micrometer.

milliohm—One-thousandth of an ohm. Letter symbol: m Ω .

millisecond—One-thousandth of a second: 10^{-3} or 0.001 second. Letter symbol: ms.

millitorr—One-thousandth of a torr.

millivolt—Abbreviated mV. One-thousandth of a volt.

millivoltmeter—A sensitive voltmeter calibrated in millivolts.

millivolts per meter—The potential difference in millivolts developed between an antenna system and ground, divided by the distance in meters between the two points.

milliwatt—Abbreviated mW. One one-thousandth of a watt. The reference level used for dB measurements.

Mills antenna—A combination of two independent fan-beam antennas placed at right angles in a cross formation, with a common center and common pencil-beam volume of low gain. Antennas are combined by switching from output phase addition to phase opposition at a constant rate to secure the angular resolution of the pencil-beam components.

MIL-STD-883B—The basic military standard for reliable semiconductors. Three classes are defined: A (aerospace), B (avionics), and C (ground).

mine detector—Also called electronic mine detector. An electronic device that indicates the presence of metallic or nonmetallic explosive mines under the ground or under water.

miniature lamp—1. A small, filament-type lamp with an operating voltage less than 60 volts. 2. Very small

tungsten lamps that are used where space is limited, as in surgical instruments such as cystoscopes. They are sometimes called grain-of-wheat lamps.

miniature sealed relay—A miniature hermetically sealed relay used in applications where space is at a premium and where high reliability is a requirement.

miniature tube—A small electron tube usually having a 7- or 9-pin base.

miniature wire—Insulated conductors of approximately 20 to 34 AWG with small overall diameters.

miniaturization—The process of reducing the minimum volume required by equipments or parts in order to perform their required functions.

minicassette—A miniature cassette system originated by Philips, allowing 15 minutes of recording per side on a narrow tape.

minicomputer—1. A loosely used term for describing any small general-purpose digital computer in the low-to-moderate price range. The approximate ceiling price used to define a minicomputer is subject to wide interpretation. 2. A machine developed primarily for the processing of a single application or the processing of a number of small applications. For example, in a distributed processing network, a minicomputer could perform a specific operation and send the volume processing through communication lines to a large mainframe. 3. A class of small, digital process-control computers sized generally around a 32-bit word, with stored programs and various memory options for data acquisition and monitoring, supervisory, or direct digital control in systems having no more than 20 or 30 control loops. 4. A small- or medium-scale computer (also called a mini), usually operated with interactive dumb terminals. A mini can operate as a single powerful workstation or as a multiuser system.

mini-disc—Abbreviated MD. A 2.5-inch optical recording and playback system that approaches the sound quality of a compact disc.

minidisk—*See* floppy disk.

minifloppy handshake—A system of transferring data from one device to another. Device A will signal that it has data ready; device B will accept that data and signal that it has it to device A, which is now released to collect more data. In the meantime device B will set an indicator that will show that it is busy with the last data until this data has been processed. The action of setting and checking these various indicators is referred to as handshaking.

minigroove—A recording having more lines per inch than the average 78-rpm phonograph record but not as many as the extended-play, long-playing, or microgroove records.

minimum-access programming—Also called minimum-latency programming, or forced coding. Programming a digital computer so information is obtained from the memory in the minimum waiting time.

minimum-access routine—A computer routine coded in a way such that the actual waiting time to obtain information from a serial memory is much less than the expected random-access waiting time.

minimum detectable signal—The signal level that just exceeds the threshold.

minimum discernible signal—Abbreviated MDS. In a receiver, the smallest input signal that will produce a discernible signal at the output. The smaller the signal required, the more sensitive the receiver.

minimum firing power—The lowest radio-frequency power that will initiate a radio-frequency discharge in a switching tube at a specified ignitor current.

minimum flashover voltage—The crest value of the lowest voltage impulse of a given waveshape and polarity that causes flashover.

minimum-latency programming—*See* minimum-access programming.

minimum-phase network—A network for which the phase shift at each frequency equals the minimum value determined solely by the attenuation-frequency characteristic.

minimum reject number—Abbreviated MRN. A number that defines the maximum number of rejects allowed for each sample given for each LTPD (lot tolerance percent defective).

minimum reliable current—As applied to relay contacts, the range at which there is insufficient energy under arcing conditions at a mating contact surface to ensure good contacting for the kind of contact material, shape, and forces employed.

minimum resistance—The resistance of a precision potentiometer measured between the wiper terminal and any terminal with the shaft positioned to give a minimum value.

minimum shift frequency—The minimum frequency at which a flip-flop can be operated in a shift-register application.

minimum-signal level—In facsimile, the level corresponding to the copy white or copy black signal, whichever is the lower.

minimum starting voltage—The minimum voltage of rated frequency applied to the control-voltage winding of a servomotor necessary to start the rotor turning at no-load conditions with rated voltage and frequency on the fixed-voltage winding.

minimum toggle frequency—The minimum frequency at which a flip-flop can be toggled. In a typical device, the maximum toggle frequency usually is about 20 percent higher.

minis—Computers that have a throughput of 32 megabits per second, and a memory size of 256 bytes of real addressable memory.

minitrack—A satellite tracking system that uses a miniature pulse-type telemeter and a precise directional antenna system, with phase-comparison tracking techniques.

minor apex face—In a quartz crystal, any one of the three smaller sloping faces near but not touching the apex (pointed end). The other three are called the major apex faces.

minor bend—A rectangular waveguide bent so that one of its longitudinal axes is parallel to its narrow side throughout the length of the bend.

minor cycle—Also called word time. In a digital computer using serial transmission, the time required to transmit one word or space between words.

minor defect—A defect that is not likely to reduce the usability of a unit for its intended purpose. It may be a departure from established standards having no significant bearing on the effective use or operation of the unit.

minor face—One of the three smaller sides of a hexagonal quartz crystal.

minor failure—A failure that has no significant effect on the satisfactory performance of a system.

minority carrier—The less predominant carrier in a semiconductor. Conduction-band electrons are the minority carriers in p-type semiconductors, since there are fewer electrons than holes. Likewise, valence-band holes are the minority carriers in n types, since they are outnumbered by the electrons.

minority emitter—An electrode from which minority carriers flow into the interelectrode region.

minor lobe—Any of the lobes, except the major lobe, that represent the radiation pattern of a directional antenna.

Minter stereo-disk playback.

minor loop—A continuous network composed of both forward and feedback elements, which is only part of the overall feedback system.

minor relay station—A tape relay station that has tape relay responsibility but does not provide an alternate route.

Minter stereo system—A stereo recording technique for producing the right and left channels. The two program channels are combined additively and recorded with a monophonic cutter. A 25-kHz note is also recorded and is frequency-modulated by the two channels combined subtractively. The sum and difference signals are then matrixed (combined) to produce the right and left channels.

MIPS—Abbreviation for millions of instructions per second. A measurement of data transmissions capacity. The more MIPS a computer has, the more powerful it is.

mirror galvanometer—A suspended-coil instrument that, instead of using a pointer to indicate the reading, employs a light beam reflected from a mirror attached to the moving coil.

mirror galvanometer oscillograph—An instrument that photographs the deflection of a light spot from a mirror attached to a moving coil. Used for recording small current variations.

mirror-reflection echoes—Multiple-reflection echoes produced when a radar beam is reflected from a large, flat surface (such as the side of an aircraft carrier) and strikes nearby targets.

mirror scale—Meter scale with a mirror arc used to align the eyeball perpendicular to the scale when taking a reading. By eliminating this human error in reading, accuracy can be improved by half.

MIS—Abbreviation for metal-insulator-silicon. Technology wherein a silicon dioxide layer is formed on a single crystal silicon substrate, and a polysilicon conductive is formed on the oxide. This layer is etched to form the electrode pattern and then doped with phosphorus to create the desired conductivity.

misfire—Failure of a mercury-pool cathode to establish an arc between the main anode and cathode during a scheduled conducting period.

mismatch—1. A condition whereby the coupled impedances inhibit optimum power transference or the source or output signal fails to match the amplifier sensitivity or the load's (i.e., speaker's) power capacity. 2. The condition in which the impedance of a load does not match the impedance of the source to which it is connected.

mismatch factor—See reflection factor, 1.

mismatch loss—The ratio between the power a device would absorb if it were perfectly matched to the source and the power it actually does absorb.

missile site radar—Phased-array radar located at a missile launch area to provide a guidance link with interceptor missiles enroute to their targets.

mission time—That element of uptime during which the item is performing its designated mission.

mistake—See error.

mistor—A magnetic-field sensing device whose resistance increases with an increase in magnetic-field intensity.

mitte-seite stereo system—German for middle-side stereo system. A technique of stereo pickup in which two directional microphones, placed close together and at right angles to each other, are oriented so that one picks up sound from directly ahead, and the other from the two sides, with maximum intensity.

Mitte-seite stereo system.

mix—To combine two or more input signals in a transducer so as to produce a single output. If the transducer is linear, the output consists of a superposition of the input signals. If the transducer is nonlinear, the output consists of the heterodyne products of the input signals.

mixed analog component (MAC) transmissions—An innovative television transmission method that separates the data, chrominance, and luminance components and compresses them for sequential relay over one television scanline. There are presently five systems being designed: A-MAC; B-MAC; C-MAC; D-MAC; and E-MAC.

mixed-base notation—A number system in which a single base, such as 10 in the decimal system, is replaced by two number bases, such as 2 and 5, used alternately.

mixed calculation—In a calculator, calculation involving more than one arithmetic mode. Saves time by permitting calculations to be handled as a single problem.

mixed dielectric capacitor—Also called bifilm capacitor. A capacitor with a dielectric consisting of a combination of plastic film and paper.

mixed highs—In color television, the method of reproducing very fine picture detail by transmitting high-frequency components as part of the luminance signal for achromatic reproduction.

mixer—1. In a sound transmission, recording, or reproducing system, a device having two or more inputs (usually adjustable) and a common output. The device combines the separate input signals linearly in the desired proportion to produce an output signal. 2. A circuit that generates output frequencies equal to the sum and difference of two input frequencies. 3. A device for blending two or more signals for special effects. 4. An audio control unit whose basic function is to combine two or more audio signals into a single, composite signal.

mixer diode—A diode, often associated with microwave circuits, that combines rf signals at two frequencies to generate an rf signal at a third frequency.

mixer ports—The input/output terminals of a mixer, identified as RF, LO, and IF. In most double balanced mixers, the LO and RF are either transformer or transmission line-coupled to the mixer diodes, and therefore have a limited low-frequency response, whereas the IF port is usually direct-coupled with an essentially unlimited low frequency response. In upconverting applications, the low frequency input signal is often applied to the IF port, with the higher-frequency output signal being taken from the RF port.

mixer tube—An electron tube that, when supplied with voltage or power from an external oscillator, performs the frequency-conversion function of a heterodyne conversion transducer.

mixing—1. Combining two or more signals—e.g., the outputs of several microphones, or the received and local-oscillator signals in a superheterodyne receiver. 2. Blending of two or more signals for special effects, while exercising individual control over the volume of each. 3. Generating output frequencies that are the sum and difference of two input frequencies.

mixing amplifier—An amplifier that combines several signals, each with a different amplitude and wave-shape, into a composite signal.

mixing point—In a block diagram of a feedback control loop, a symbol indicating that the output is a function of the inputs at any instant.

mksa—Meter-kilogram-second-ampere.

mksa electromagnetic system of units—Also called the Giorgi system. A system in which the fundamental units are the meter, kilogram, second, and ampere.

MLM—See multilayer metallization.

MLS—Abbreviation for microwave landing system. A microwave system that creates a fan-shaped beam over a wide volume of airspace so planes can use various approaches to a runway during bad weather.

mm—Letter symbol for millimeter.

mmf or mmfd—Abbreviation for micromicrofarad; this term is obsolete and has been replaced by picofarad.

mm Hg—Millimeters of mercury. A measure of absolute pressure, being the height of a column of mercury that the air or other gas will support. Standard atmospheric pressure will support a mercury column 760 millimeters high (760 mm Hg). Any value less than this represents some degree of vacuum.

MMIC—Abbreviation for monolithic microwave integrated circuit. A combination of active elements (diodes and transistors) and passive elements (resistors, capacitors, inductors, and transmission lines) on a single GaAs (gallium arsenide) substrate. MMICs replace conventional "chip and wire" microwave circuits. As amplifiers, attenuators, or switches at microwave frequencies, MMICs offer benefits of reduced size, lower unit cost, and higher reliability. An integrated circuit design.

mnemonic—1. A term describing something used to assist the human memory. 2. A method of expressing complicated words, names, or phrases so as to render them easy to remember, usually by using the first letter or letters of each major syllable of the original. 3. The art of improving the efficiency of the memory (in computer storage). Abbreviation of instructions used in computer language programming. 4. An abbreviation or word that stands for another word or phrase.

mnemonic code—1. Computer instructions written in a form the programmer can remember easily, but which must be converted into machine language later. 2. A memory jogger. 3. Computer instructions written in brief, easy-to-learn, symbolic or abbreviated form. Mnemonic code is also recognizable by the assembly program. For example, ADD, SUB, CLR, and MOV are mnemonic codes for instructions that will be executed as machine code.

mnemonic language—A programming language that is based on easily remembered symbols and that can be assembled into machine language by the computer.

mnemonic operation codes—Computer instructions that are written in a meaningful notation, for example: ADD, MPY, STO.

mnemonic symbol—A symbol chosen so that it assists the human memory; for example, the abbreviation MPY used for "multiply."

MNOS—Abbreviation for metal-nitride-oxide semiconductor.

mobile operation—Radiocommunication conducted while in motion or during halts at unspecified locations.

mobile radio service—Radio service between a fixed location and one or more mobile radio stations, or between mobile stations.

mobile radiotelephone—System providing telephone service to a station located in a mobile vehicle, using radio circuits to a base station that is connected to a central telephone office.

mobile receiver—The radio receiver in an automobile, truck, or other vehicle.

mobile-relay station—A type of base station in which the base-station receiver automatically turns on the base-station transmitter that then retransmits all signals received by the base-station receiver. Such a station is used to extend the range of mobile units and requires two frequencies for operation.

mobile service—A radiocommunication service between mobile and fixed stations, or between mobile stations. Depending on whether one or more of the earth stations are on land, sea, or air, the service is called land mobile, maritime mobile, or aeronautical mobile.

mobile station—A radio station intended for use while in motion or during halts at unspecified points. Included are hand- and pack-carried units.

mobile telemetering—Electric telemetering between moving objects, where interconnecting wires cannot be used.

mobile telephone service—1. Telephone service between a fixed base station and several mobile stations in vehicles. 2. Telephone service from mobile stations into the commercial telephone system. 3. Radiotelephone service provided to motor vehicles, railroad trains, and airplanes.

mobile transmitter—A radio transmitter installed and operated in a vessel, land vehicle, or aircraft.

mobility—Symbolized by the Greek letter μ (μ). 1. The ease with which carriers move through a semiconductor when they are subjected to electric forces. In general, electrons and holes do not have the same mobility in a given semiconductor. Also, their mobility is higher in germanium than in silicon. Normally expressed in terms of the average drift velocity attained by the type of carrier concerned per unit electric field intensity. 2. The velocity of a charged particle attained under the action of an applied electric field. Units are $\text{cm}^2/\text{V}\cdot\text{Sec}$.

mobius counter—See Johnson counter.

modal dispersion—A fiber bandwidth-limiting factor caused by differences in the propagation characteristics of the various modes in a multimode fiber.

mod/demod—Abbreviated form of modulating and demodulating.

mode—1. One of several types of electromagnetic wave oscillation that may be sustained in a given resonant system. Each type of vibration is designated as a particular mode and has its own particular electric- and magnetic-field configurations. 2. One of several methods of exciting a resonant system. The term has also been used to describe the existence of a number of different input voltages that allow operation of a klystron at the same frequency. 3. A computer system of data representations (e.g., the binary mode). 4. The most frequent value in a series of measurements or operations. 5. The characteristic of a quantity being suitable for integer or floating-point computation. 6. The most common or frequent value in a group of values. 7. The pattern of an electromagnetic field within an optical fiber. A fiber that can propagate only one field pattern is referred to as a single-mode fiber; a fiber propagating more than one field pattern in a multimode fiber.

mode coupling—The interaction or exchange of energy between similar modes.

mode filter—A waveguide filter designed to separate waves of the same frequency but of different transmission modes.

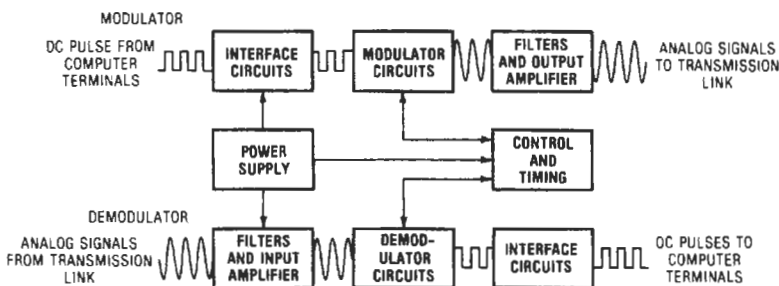

mode hopping—The random shifting of laser output energy from one mode to another for short durations, usually in the microsecond range. The modes are generally closely spaced.

mode jump—A change in the mode of magnetron operation from one pulse to the next. Each mode represents a different frequency and power level.

model—1. An approximate representation of a process or system that tries to relate (usually mathematically) a part or all of the variables in the system so that a better understanding of the system is attained. 2. A geometrically accurate and complete representation of a real object stored in a CAD/CAM data base.

mode-locked laser—A laser that functions by modulation of the energy content of each mode internally to give rise selectively to energy bursts of high-peak power and short duration.

modem—Acronym for *modulator/demodulator*, also known as a data set. 1. A device that transforms a typical two-level computer signal into a form suitable for transmission over the telephone network (for example, conversion of a two-level signal into a two-frequency sequence of signals). 2. A device that modulates and demodulates signals transmitted over communication facilities. 3. A device that performs modulation in the form of signal conversion, interfacing computers or computer peripheral equipment to the telephone line. Instead of trying to send a logic 0 or 1 dc voltage level over phone lines where voltage transients or noise pulses could be interpreted as false signals at the other end of the line and where transformer coupling is used, the modem changes the logic 0 or 1 into pulse audio tones. The tones travel over the phone line and enter a companion modem at the other end of the line and are converted back into 1s and 0s to properly interface and communicate with a computer or computer peripheral equipment. 4. A modulator-demodulator, whose primary function is to convert input digital data to a form compatible with basically analog transmission lines. Modulation is the digital-to-analog conversion process; demodulation is the reverse, whereby transmitted analog signals are reconverted to digital data compatible with the receiving data-handling equipment. In the process of carrying out this primary function, the modem must be compatible with the data communications equipment at its digital interface as well as with the telephone line at its analog interface. 5. A device that converts electrical signals to telephone tones and back again. The conversion occurs through acoustic coupling (placing speakers near the phone) or direct coupling to the line, which provides superior frequency response. Most modems use the RS-232C interface standard. 6. A device that converts signals from digital to analog and vice versa. The word modem is a contraction of the two main functions of the unit: modulator (converts digital to analog) and demodulator (converts analog to digital). 7. A device that modulates

Modem.

and demodulates signals transmitted over communications facilities; that is, a device used to convert digital signals into analog (voice-like) signals for transmission over a telephone line. At the other end of the line another modem converts the analog signals back into digital form.

mode number—1. In a reflex klystron, the number of whole cycles that a mean-speed electron remains in the drift space. 2. The number of radians of phase shift resulting from going once around the anode of a magnetron divided by 2π .

mode of failure—See failure mode.

mode of resonance—A form of natural electromagnetic oscillation in a resonator. It is characterized by an unvarying field pattern.

mode of transmission propagation—1. A form of guided-wave propagation characterized by a particular field pattern that intersects the direction of propagation. The field pattern is independent of its position along the waveguide. For a uniconductor waveguide, it also is independent of frequency. 2. In a vibrating system, the state that corresponds to one of the resonant frequencies.

mode of vibration—The pattern formed by the movement of the individual particles in a vibrating body (e.g., piezoelectric crystal). This pattern is determined by the stresses applied to the body, the properties of the body, and the boundary conditions. The three common modes of vibration are flexural, extensional, and shear.

mode purity—The freedom of an atr tube from undesirable mode conversion while the tube is in its mount.

mode separation—In an oscillator, the difference in frequency between resonator modes of oscillation.

mode shift—In a magnetron, the change in mode during a pulse.

mode skip—Failure of a magnetron to fire during each successive pulse.

mode transducer—Also called mode transformer. A device that transforms an electromagnetic wave from one mode of propagation to another.

mode transformer—See mode transducer.

modification—The physical alteration of a system, subsystem, etc., for the purpose of changing its designed capabilities or characteristics.

modified constant-voltage charge—The charging of a storage battery in which the voltage of the charging circuit is held substantially constant, but a fixed resistance is inserted in the battery circuit, producing a rising voltage characteristic at the battery terminals as the charge progresses.

modified index of refraction—Also called modified refractive index. In the troposphere, the index of refraction at any height increased by h/a , where h is the height above sea level and a is the mean geometrical radius of the earth. When the index of refraction in the troposphere is horizontally stratified, propagation over a hypothetical flat earth through an atmosphere with the modified index of refraction is substantially equivalent to propagation over a curved earth through the real atmosphere.

modified refractive index—See modified index of refraction.

modifier—A device that alters an instruction but does not change the form of energy (for example, the changing of electrical input signals into electrical output signals).

moding—A defect of magnetron oscillation in which the magnetron oscillates in one or more undesired modes.

modular—1. Made up of modules. 2. Dimensioned according to a prescribed set of size increments. 3. A partitioning scheme for a family of single-board micro-computer family circuit cards wherein system and I/O

functions of various types are grouped and organized into modules (a memory module, for example). Each of the modular circuit board elements also includes a bus interface to allow intercommunication. The benefit to the system designer is that various functions can be included only to the degree needed for a specific application. 4. Having dimensions which are integral multiples of a unit of length called a module. 5. Composed of subunits. Computer systems and programs are made this way to make them easier to change or expand. 6. A design technique that permits a device or system to be assembled from interchangeable components; such a system or device can be expanded or modified simply by adding another module.

modular connector—A connector in which similar or identical sections can be assembled together to provide the best connector type or size for the application.

modulate—To vary the amplitude, frequency, or phase of a wave by impressing one wave on another wave of constant properties.

modulated amplifier—In a transmitter, the amplifier stage where the modulating signal is introduced and modulates the carrier.

modulated-beam photoelectric system—An intrusion-detector system that provides reliable beam ranges of several thousand feet. This is done by interrupting the light beam at the source with a rotating punched or slotted disc. In this way, the phototube output is converted to an ac signal, which can then be easily amplified.

modulated carrier—A radio-frequency carrier in which the amplitude or frequency has been varied by, and in accordance with, the intelligence to be conveyed.

modulated continuous wave—Abbreviated MCW. A wave in which the carrier is modulated by a constant audio-frequency tone. In telegraphy service, the carrier is keyed to produce the modulation.

modulated light—Light whose intensity has been made to vary in accordance with variations in an audio-frequency or code signal.

modulated oscillator—An oscillator whose output frequency is varied by an input signal.

modulated photoelectric alarm system—A photoelectric alarm system in which the transmitted light beam is modulated in a predetermined manner and in which the receiving equipment will signal an alarm unless it receives the properly modulated light.

modulated signal generator—A device that produces an output signal that may be changed in amplitude and/or frequency according to a desired pattern. It is calibrated in units of both power (or voltage) and frequency.

modulated stage—The radio-frequency stage to which the modulator is coupled and in which the continuous wave (carrier wave) is modulated in accordance with the system of modulation and the characteristics of the modulating wave.

modulated wave—A carrier wave in which the amplitude, frequency, or phase varies in accordance with intelligence signal being transmitted.

modulating amplifier using variable reactance—A very-high-frequency electron-beam parametric amplifier with bandpass characteristics that are independent of gain, and which is unconditionally stable.

modulating electrode—In a cathode-ray tube, an electrode to which a potential is applied to control the magnitude of the beam current.

modulating signal—See modulating wave.

modulating wave—Also called modulating signal, or simply signal. A wave that varies some characteristic (i.e., frequency, amplitude, phase) of the carrier.

modulation—1. The process of modifying some characteristic of a wave (called a carrier) so that it varies

in step with the instantaneous value of another wave (called a modulating wave or signal). The carrier can be a direct current, an alternating current (provided its frequency is above the highest frequency component in the modulating wave), or a series of regularly repeating, uniform pulses called a pulse chain (provided their repetition rate is at least twice that of the highest frequency to be transmitted). 2. The controlled variation of frequency, phase, and/or amplitude of a carrier wave of any frequency in order to transmit a message. 3. In fiber optics, the manner in which information is coded into light for transmission through a fiber. The modulation method may be either pulse modulation (digital) or intensity modulation (analog). 4. The process of varying one signal with another. 5. The imposing of a signal on some type of transmission or storage medium, such as a radio carrier or magnetic tape. 6. The process, or results of the process, whereby some characteristic of one signal is varied in accordance with another signal. The modulated signal is called the carrier and may be modulated in three fundamental ways: by varying the amplitude (amplitude modulation) by varying the frequency (frequency modulation) or by varying the phase (phase modulation). 7. The process by which some characteristic of a higher frequency wave is varied in accordance with the amplitude of a lower frequency wave.

modulation capability — The maximum percentage of modulation possible without objectionable distortion.

modulation code — A code used to cause variations in a signal in accordance with a predetermined scheme; normally used to alter or modulate a carrier wave to transmit data.

modulation distortion — Distortion occurring in the radio-frequency amplifier tube of a receiver when the operating point is at the bend of the grid-voltage/plate-current characteristic curve. As a result, the plate-current changes are greater on positive than on negative half-cycles. The effect is equivalent to an increase in the percentage of modulation.

modulation envelope — A curve, drawn through the peaks of a graph, showing how the waveform of a modulated carrier represents the waveform of the intelligence carried by the signal. The modulation envelope is the intelligence waveform.

Modulation envelope.

modulation factor — In an amplitude-modulated wave, the ratio of half the difference between the maximum and minimum amplitudes to the average amplitude. This ratio is multiplied by 100 to obtain the percentage of modulation.

modulation frequency — That signal which causes the output frequency of an oscillator to be modulated.

modulation index — 1. In frequency modulation with a sinusoidal modulating wave, the ratio of the frequency deviation to the frequency of the modulating wave. 2. A measure of the degree of modulation.

modulation indicator — A relative indicator that glows brighter and brighter as the modulation level approaches 100 percent. It gives the operator some idea of how fully he or she is modulating the carrier.

modulation meter — An instrument that measures the modulation percentage of an amplitude modulated signal and displays the results on a scale or dial.

modulation monitor — See modulation meter.

modulation noise — Also called noise behind the signal. 1. The noise caused by the signal, but not including the signal. 2. The noise produced on playback of a tape that is a function of the instantaneous amplitude of the signal. It is caused by poor particle dispersion and surface irregularities.

modulation percentage — The modulation factor multiplied by 100.

modulation plan — The arrangement by which the individual channels or groups of channels are modulated to a final frequency allocation.

modulation ratio — For an electrically modulated source, the number obtained by dividing the percentage of radiation modulation by the percentage of current modulation.

modulation rise — An increase in the modulation percentage. It is caused by a nonlinear tuned amplifier, usually the last intermediate-frequency stage of a receiver.

modulation transfer function — Abbreviated MTF. Also called sine-wave response, and contrast transfer function. 1. The ratio of input modulation to output modulation. 2. A plot of the video output amplitude as a function of TV line number for a sine-wave-modulated input, i.e., a bar pattern with sine-wave density variation serving as the object for the TV camera. The output video amplitude, measured by an oscilloscope, is calibrated at 100 percent for small line numbers (wide lines). 3. The function, usually a graph, describing the modulation of the image of a sinusoidal object as the frequency increases. The ratio of the modulation in the image to that in the object.

modulator — 1. A device that effects the process of modulation. 2. In radar, a device for generating a succession of short energy pulses that cause a transmitter tube to oscillate during each pulse. 3. An electrode in a spaciator.

modulator crystal — A crystal that is used to modulate a polarized light beam by the use of Pockel's effect. Useful as a modulator in laser systems.

modulator driver — A transmitter circuit that produces a pulse to be delivered to the control grid of the modulator stage.

modulator glow tube — A cold-cathode recorder tube used for facsimile and sound-on-film recording. It provides a modulated, high-intensity, point-of-light source.

modulator stage — The last stage through which the signal that modulates the radio-frequency wave is passed.

module — 1. A unit in a packaging scheme displaying regularity and separable repetition. It may or may not be separate from other modules after initial assembly. Usually all major dimensions are in accordance with a prescribed series of dimensions. 2. A packaging concept in which identical forms are used. 3. A complete sub-assembly of a larger system combined in a single package. 4. An interchangeable plug-in item containing electronic components, which may be combined with other interchangeable items to form a complete unit. 5. A collection of modules or a collection of software items in any

combination in computer software. 6. A section of software that has well-defined inputs and outputs and may be tested independently of other software. 7. An encapsulated all-solid-state control circuit. 8. An equipment unit capable of being combined with other similar units to form a larger unit. 9. Any assembly of interconnected components that constitutes an identifiable item, device, instrument, or piece of equipment.

modulo—A term used to express the maximum number of states for a counter; this term is used to describe several packet-switched network parameters, such as packet number (usually set to modulo 8, counted from 0 to 7). When the maximum count is exceeded, the counter is reset to 0.

modulo-*n* counter—A counter with *n* unique states. *See also* programmable counter.

modulus—Abbreviated mod. 1. An integer designating the number of states through which a counter sequences during each cycle. 2. The number of distinct states that a counter has. For example, the modulo-10 counter has a modulus of 10 and therefore has 10 distinct states.

moiré—1. A wavy or satiny effect produced by the convergence of lines. Usually appears as a curving of the lines in the horizontal wedges of the test pattern and is most pronounced near the center, where the lines forming the wedges converge. A moiré pattern is a natural optical effect when converging lines in the picture are nearly parallel to the scanning lines. To a degree this effect is sometimes due to the characteristics of color picture tubes and of image-orthicon pickup tubes (in the latter, it is termed mesh beat). 2. A coarse pattern of shading that occurs in a facsimile system when half-tone material is scanned. 3. In television, the spurious pattern in the picture resulting from interference beats between two sets of periodic structures in the image.

moiré effect—A fringe pattern arising from the interference between two superimposed line patterns. In a monitor it comes from the interference between the shadow mask pattern and the video information (video moiré) or between the shadow mask pattern and the horizontal line pattern (scan moiré). Autoscan (MultiSync) monitors, which operate over a range of scanning frequencies, may sometimes exhibit moiré in certain video modes.

moisture absorption—The amount of moisture (in percentage) that an insulation will absorb. The figure should be as low as possible when the insulation is to be used in a moist environment.

moisture repellent—Having properties such that moisture will not penetrate.

moisture resistance—The ability of a material not to absorb moisture, either from the air or from being immersed in water.

moisture resistant—Having characteristics such that exposure to a moist atmosphere will not readily lead to a malfunction.

mol—Abbreviation for molecular weight.

mold—In disc recording, a metal part derived from a master by electroforming. It is a positive of the recording (i.e., it has grooves similar to those of a recording and thus can be played).

molded capacitor—A capacitor that has been encased in a molded plastic insulation.

molded carbon potentiometer—A potentiometer in which a carbon resistance element and all other parts of the potentiometer are molded together.

molding—A process using pressure to apply accurately dimensional, specifically shaped jackets to parts or assemblies. This process usually uses costly heavy-machined metal molds.

moletronics—Abbreviation for molecular electronics.

molecular circuit—1. *See* monolithic integrated circuit. 2. An electronic circuit demonstrating a measurable input and output, where the portions performing various functions such as resistance or capacitance are indistinguishable as discrete areas.

molecular circuitry—*See* morphological circuitry.

molecular clock—A device for time measurement based on an electromagnetic oscillation of extremely stable frequency from a beam of the rotation spectrum, the vibration or inversion of a particular molecule, and a counting device.

molecular electronics—Abbreviated moletronics. 1. The science of making a single block of matter perform the function of a complete circuit. This is done by merging the function with a material, using solid-state functional blocks. 2. Electronics on a molecular scale, dealing with the production of complex circuitry in semiconductor devices with integral elements processed by growing multizoned crystals in a furnace for the ultimate performance of electrical functions.

molecular integrated circuit—An integrated circuit such that the identity and location of specific electric elements cannot be determined even by microscopic disassembly of the material of which the circuit is formed. In contrast to a conventional microelectronic circuit, the molecular integrated circuit can be defined only by function, which in turn can be described only by mathematical models and incremental circuit representation.

molecular technique—A practice method of causing a single piece of material or a crystal to provide a complete circuit function.

molecular weight—Abbreviated mol. Also known as relative molecular mass. The sum of the weights of all the atoms in a molecule, expressed relative to $1/12$ of the mass of a carbon-12 atom.

molecule—In any substance, the smallest particle that still retains the physical and chemical characteristics of that substance. A molecule consists of one or more atoms of one or more elements. Sometimes two entirely different substances may have similar chemical elements, but their atoms will be arranged in a different order.

molybdenum—A metallic element (chemical symbol, Mo; atomic number, 42; atomic weight, 95.95) sometimes used for the grid and plate electrodes of vacuum tubes.

momentary contact—Closure of a normally open switch for a brief period.

momentary contact switch—A mercury switch designed to make contact for only a brief transitory interval while the mercury moves from one extreme position to another.

momentary loss of power—A short interruption of power to the total equipment.

momentary start—An electrical signal for starting a timer that is of any duration shorter than the time setting.

momentary switch—1. A switch that returns to its normal circuit condition when the actuating force is removed. 2. A spring-loaded contact that, when pressed, closes two contacts. When pressure is removed, contacts open.

monaural—Describing sound reproduction using only one source of sound and giving a monophonic effect. *See* monophonic.

monaural channel unbalance—The ratio of the outputs from the right and left channels with a monaural signal applied to the input.

monaural recorder—Literally, a tape recorder intended for listening with one ear only; however, in popular usage refers to single-channel recorders, as

distinguished from multichannel (stereophonic, binaural, etc.) types. More correctly but less universally called monophonic recorder.

monitor—1. To listen to a communication service, without disturbing it, to determine its freedom from trouble or interference. 2. A device (e.g., a receiver, oscilloscope, teleprinter, etc.) used for checking signals. 3. A software package or a hardware device that can be used to measure the performance of a system or the utilization of specific devices. 4. Any device used to observe or measure a parameter. 5. Any device for listening incidentally to an audio signal that is primarily directed to some other purpose at that moment. A monitor loudspeaker is used for auditioning a recording or radio program incidentally to its committal to tape or its broadcast. 6. The operator of a television monitoring system who selects one out of several camera images for broadcasting. 7. A TV set without a tuner used to directly display the composite video signal from a camera, videotape recorder, or special-effects generator. 8. A controller of the operation of the various programs available, the monitor can access the editor, assembler, or other programs. 9. A program that controls a computer's basic operation, telling it how and where to acquire the programs and data, where to store them, and how to run them. 10. A device for video viewing connected directly to the camera output. A true monitor does not incorporate channel selector components or audio components.

monitored fast forward—A feature in a cartridge deck whereby the playback amplifier is left on at low volume during fast forward so the user can hear the program running through at the faster speed, to spot or cue up to the desired program.

monitor head—A playback head that is separated from the record head, enabling the recordist to listen to what is coming off the tape a fraction of a second after it has been recorded and while the recording is still in progress. Without a monitor head, a tape must be recorded to its end and then rewound and replayed before the recordist can evaluate the tape. On some cassette decks with monitor capability, the monitor head is not completely separate, but is built into the same shell as the record head.

monitoring—1. Observing the characteristics of transmitted signals as they are being transmitted. 2. Listening to a communication service without disturbing it to determine its quality or freedom from trouble or interference.

monitoring amplifier—A power amplifier used primarily for evaluation and supervision of a program.

monitoring key—A key that, when operated, permits an attendant or operator to listen on a telephone circuit without causing appreciable impairment of transmission on the circuit.

monitoring radio receiver—A radio receiver for checking the operation of a transmitting station.

monitors—Programs that control the operation of an entire computer system. They often contain routines that tell the computer how to communicate with the outside world and how to allocate resources.

monitor systems—Programs that supervise other programs and keep computers functioning efficiently with a minimum of assistance from human operators.

monkey chatter—Garbled speech or music heard along with a desired program. This interference occurs when the side frequencies of an adjacent-channel station beat with the signal from the desired station.

monoboard microcomputer—*See* single-board microcomputer.

monobrid—A method of manufacturing an integrated circuit by using more than one monolithic chip within the same package.

monobrid circuit—An integrated circuit using a combination of monolithic and multichip techniques by means of which a number of monolithic circuits or a monolithic device in combination with separate diffused or thin-film components are interconnected in a single package.

monochromatic—1. Pertaining to or consisting of a single color. 2. Radiation of a single wavelength.

monochromatic emissivity—*See* total emissivity.

monochromaticity—The degree of response to one color.

monochromatic light—Light consisting of just one wavelength. No light is completely monochromatic. The closest approach is particular lines in the mercury 198 spectrum excited in a discharge tube with no electrodes.

monochromatic sensitivity—The response of a device to light of a given color only.

monochromator—An instrument used to isolate narrow portions of the spectrum by making use of the dispersion of light into its component colors.

monochrome—Also called black-and-white in referring to television. 1. Having only one chromaticity—usually achromatic, or black and white and all shades of gray. 2. Black and white with all shades of gray.

monochrome channel—In a color television system, any path intended to carry the monochrome signal (although it may carry other signals also).

monochrome channel bandwidth—The bandwidth of the path that carries the monochrome signal.

monochrome signal—1. In a monochrome TV transmission, the signal wave that controls the luminance values in the picture. 2. In a color-television transmission signal wave, the portion with major control of luminance, whether displayed in color or monochrome.

monochrome television—Also called black-and-white television. Television in which the final reproduced picture is monochrome. That is, it has only shades of gray between black and white.

monochrome transmission—Also called black-and-white transmission. 1. In television, the transmission of a signal wave that represents the brightness (luminance) values in the picture, but not the color (chrominance) values.

monoclinic—A crystal structure in which two of the three axes are perpendicular to the third, but not to each other.

monocord switchboard—A local-battery telephone switchboard in which each line terminates in a single jack and plug.

monocrystal—A crystal of material that has a continuous lattice structure and orientation throughout its volume, in contrast with the multigrain structure of a polycrystal. Almost all semiconductor devices are fabricated from monocrystalline material.

monocrystalline—Material made up of a single continuous crystal.

monoergic—A type of emission in which the particles or radiations are produced with a small energy spread (i.e., a "line spectrum").

monofier—A complete master oscillator and power amplifier system contained in a single evacuated envelope. It is equivalent electrically to a stable low-noise oscillator, an isolator, and a two- or three-cavity klystron amplifier.

monofilament—A single-strand filament, as opposed to a braided or twisted filament.

monogroove stereo—Also called single-groove stereo. A stereo recording in which both channels are contained in one groove.

monolithic—1. Existing as one large, undifferentiated whole. 2. Refers to the single slice of silicon substrate on which an integrated circuit is built; hence, monolithic integrated circuit. 3. Elements or circuits formed within a single semiconductor substrate.

monolithic ceramic capacitor—An electrostatic capacitor that is constructed by cofiring alternate layers of metal (electrodes) with carefully selected ceramic (dielectric) materials.

Monolithic ceramic capacitor.

monolithic circuit—A monolithic semiconductor integrated circuit has all circuit components manufactured in or on top of a single crystal semiconductor material. Interconnections between the component parts within a given circuit are made by means of metallization patterns, and the individual parts are not separable from the complete circuit. Hence, the monolithic circuit is often referred to as a fully integrated circuit.

monolithic filter—A filter whose operations are based on the use of deposited electrode pairs acting as shear or thickness-mode resonators separated by nonelectrode regions that act as acoustic coupling elements. The entire filter is on a single quartz or ceramic substrate.

monolithic hybrid—Hybrid circuit built on a multilayer semiconductor substrate. Semiconductor elements are actually formed within the substrate in a process much like that used to build a monolithic IC. Additional components can be soldered or chemically bonded to the substrate, but components usually are fabricated within the substrate.

monolithic IC—See monolithic integrated circuit.

monolithic integrated circuit—Abbreviated MIC.

1. An integrated circuit whose elements are formed *in situ* upon or within a semiconductor substrate, with at least one of the elements formed within the substrate. See also integrated circuit, 1. To further define the nature of a monolithic integrated circuit, additional modifiers may be prefixed. Examples: pn junction-isolated monolithic integrated circuit, dielectric-isolated monolithic integrated circuit, or beamlead monolithic integrated circuit. 2. The physical realization of electronic circuits or subsystems from a number of extremely small circuit elements inseparably associated on or within a continuous body or a thin film of semiconductor material. 3. An integrated circuit that is fabricated completely on a single chip and which contains no thin film or discrete components. (As opposed to hybrid IC.) 4. A complete electronic circuit fabricated as an inseparable assembly of circuit elements in a single small structure. It cannot be divided without permanently destroying its intended electronic function.

5. An integrated circuit in which all components are created by pn junctions grown on a single chip of silicon crystal. 6. An electronic circuit formed within a single small chip of crystalline semiconductor material, usually silicon. Typically the chip is contained in a plastic or ceramic package. Electrical connection to package leads is made by fine wire, which is welded to metal pads on the chip and to the package leads. The advantages of integrated circuits include small size and extremely high reliability.

monolithic microcircuit—See monolithic integrated circuit.

monolithic microwave integrated circuit—See MMIC.

monolithic™ capacitor—A trademark of the Sprague Electric Company for a multilayer monolithic ceramic capacitor.

monomer—A single molecule that can join with another monomer or molecule to form a polymer or molecular chain.

monomode fiber—An optical fiber used for extremely long distance needs, with a core so tiny that all of the photons essentially have to travel in a straight line. These fibers may be used in transatlantic cable, with repeaters located at 12-mile (19-km) intervals. Since the photons have little chance to disperse, the light pulses fed into the fiber can in theory be so very rapid—100 billion bits a second—that a single fiber could carry the digital equivalent of tens of thousands of voices simultaneously. (However, no laser now known can flash fast enough to exploit fully the capacity of a monomode fiber.)

monophonic—Also called by the older term monaural. 1. Pertaining to audio information on one channel (i.e., as opposed to binaural or stereophonic). Monophonic and monaural are usually, although not necessarily, associated with a one-speaker system. 2. Single-channel sound.

monophonic recorder—See monaural recorder.

monopinch—Antijam application of the monopulse technique in which the error signal is used to provide discrimination against jamming signals.

monopole—A stub antenna fed against a ground plane.

monopole antenna—A vertical antenna with a voltage node at the lower end and a current node at the top that is 0.25 wavelength at the operating frequency.

monopulse—A method of determining azimuth and elevation angles simultaneously.

monopulse radar—Radar using a receiving antenna system having two or more partially overlapping lobes in the radiation pattern. Sum and difference channels in the receiver compare the amplitudes or phases of the antenna outputs.

monopulse tracking—A form of telemetry tracking that compares the phase of the carrier received simultaneously at four points on a plane (two elevation and two azimuth references) and positions the antenna so that all four signals are in phase, or equidistant from the source of radiation. A variation of the monopulse tracking technique is the scan-coded or single-channel monopulse tracking system.

monorange speaker—A speaker that provides the full spectrum of audio frequencies.

monoscope—Also called phasmajetron or monotron. An electron-beam tube in which the picture signal is generated by scanning an electrode, parts of which have different secondary-emission characteristics.

monoscope cathode-ray tube—A character-generator CRT that functions on the principle of secondary emission. The target holds a set of aluminum characters, select characters being scanned by the electron

beam. The secondary emission from the target is gathered by the collector and becomes a video signal to be transmitted to and converted in other cathode-ray tubes.

monospacing—Method of printing in which each character printed takes up the same amount of space horizontally, irrespective of the size of the character.

monostable—Also called single-shot or one-shot. 1. A term used to describe a circuit that has one permanently stable state and one quasi-stable state. An external trigger causes the circuit to undergo a rapid transition from the stable state to the quasi-stable state, where it remains for a time and then spontaneously returns to the stable state. 2. A type of multivibrator that has one stable state. The integrated-circuit version usually includes input gating and sometimes a Schmitt trigger. 3. A system that has an at-rest bias causing one output condition consistently until appropriate input signaling occurs.

monostable circuit—A circuit capable of two states of operation in which only one such state is stable; i.e., if triggered into the unstable state, the circuit will (after a controllable time interval) return to the stable state without external intervention.

monostable multivibrator—Also called one-shot multivibrator, single-shot multivibrator, or start-stop multivibrator. 1. A circuit having only one stable state, from which it can be triggered to change the state, but only for a predetermined interval, after which it returns to the original state. 2. A multivibrator having one stable and one semistable condition. A trigger is used to drive the unit into the semistable state, where it remains for a predetermined time before returning to the stable condition. 3. A half-analog/half-digital circuit that produces a pulse on its output in response to a trigger signal at its input. The output pulse width is determined by a resistor-capacitor network. 4. A multivibrator that delivers one output pulse, of adjustable width, for each input pulse received.

Circuit.

Output.

Monostable multivibrator.

monostatic reflectivity—The characteristic of a reflector that reflects energy only along the line of the incident ray (e.g., a corner reflector).

monotone—A single musical tone unvaried in pitch.

monotonic DAC—A digital-to-analog converter that has an analog output that is a continuously increasing function of the input.

monotonicity—1. A measure of the ability of a converter (either d/a or a/d) to produce an output in response to a continuously increasing input signal (a/d) or count (d/a) without decreasing in value or skipping codes. 2. Parameter for a d/a converter. It means that there is always an increase in the output level for each increase in digital input. If the output decreases, the converter is nonmonotonic and can seldom be used to its full resolution. 3. In a d/a converter, if the output analog signal either increases or stays the same for an increase in input digital code, it is termed monotonic. In an a/d converter, if the output digital code increases or stays the same for a 1-lsb increase in input voltage, it is termed monotonic. If a data converter's differential linearity lies within ± 1 lsb, the device will be monotonic. Monotonicity is especially important in control loops where convergence is necessary. 4. In analog-to-digital conversion, indicates that the digital output never exhibits a decrease between one conversion and the next, as the analog input increases steadily from zero to rated maximum.

monotron—See monoscope.

Monte Carlo analysis—A mathematical technique that, by randomly changing component values, predicts the effect of statistical variations on circuit performance.

Monte Carlo method—Abbreviated MCM. 1. A computer technique in which a number of possible models under study are mathematically constructed from constituents selected at random from representative populations. 2. Any procedure that involves statistical sampling techniques in order to obtain an approximate solution of a mathematical or physical problem.

Monte Carlo simulation—A subset of digital simulation models based on random or stochastic processes.

MOPA—Acronym for master oscillator-power amplifier.

morphological circuitry—Also called molecular circuitry. A circuit made from a material in which the molecular structure has been arranged to perform a certain electrical function.

Morse code—A system of dot-and-dash signals developed by Samuel F. B. Morse and now used chiefly in wire telegraphy.

Morse code.

Morse sounder—1. A telegraph receiving instrument that produces a sound at the beginning and end of each dot and dash. From these sounds, a trained operator can interpret the message. 2. A device consisting of an electromagnet with a spring-loaded armature that is used for the reception of Morse coded signals. The start of a mark signal produces a sharp “click” sound, and the end of the signal a “clack” sound.

Morse telegraphy—Telegraphy in which the Morse code or its derivative is used—specifically, the International (also called continental) or American Morse code.

MOS—Abbreviation for metal-oxide semiconductor.

mosaic—The light-sensitive surface of an iconoscope or other television camera tube. In one form, it consists of millions of tiny silver globules on a sheet of ruby mica. Each globule is treated with cesium vapor to make it sensitive to light. The globules retain a positive charge when bombarded with light and absorb electrons from a scanning beam in proportion to the amount of light they have received.

mosaic detector—A device in which a number of active elements are arranged in an array. It is generally used as an imaging device.

mosaic-lamp display—A form of display made up of seven straight line segments that can be used to form all digits. An individual lamp behind each segment lights to form each digit.

MOS capacitor—A capacitor in which a silicon-oxide dielectric layer and a metal top electrode are deposited on a conducting semiconductor region that acts as the bottom electrode.

MOS device—Semiconductor component (typically, in an IC) formed by metal-oxide semiconductor process. In an MOS device, current can flow in either of two directions, whereas in a bipolar semiconductor current flows in only one direction.

MOSFET—Abbreviation for metal-oxide semiconductor field-effect transistor. Sometimes called insulated-gate field-effect transistor (IGFET).

MOSFET (n-channel enhancement type).

MOS insulated-gate field-effect transistor—A semiconductor device consisting of two electrodes (source and drain) diffused into a silicon substrate and separated by a finite space, thus forming a majority-carrier conducting channel. A metal electrode (gate) is placed above and insulated from the channel.

MOS monolithic IC—A single-chip integrated circuit, consisting largely of interconnected unipolar active-device elements or MOS field-effect devices. This class of circuits results in higher equivalent parts density.

most significant bit—Abbreviated MSB. 1. The highest-order bit or the bit with the greatest weight. 2. The bit in the leftmost position.

most significant digit—Abbreviated MSD. 1. Number at the extreme left of a group of numbers. Example, 6937. Digit 6 is the MSD. Does not apply to number 0 when in the MSD position. 2. In a binary number, it is the digit with the highest weighting.

mother—In disc recording, a mold electroformed from the master.

motherboard—1. The main board in a computer, into which the circuits are plugged. 2. The main board in a computer that holds the CPU chip, the ROM, the RAM, and sometimes coprocessors. 3. A circuit board that accommodates plug-in cards or daughterboards and makes appropriate interconnecting terminations between them. 4. A printed circuit board to which one or more other circuit boards may be assembled and connected. 5. The main printed circuit board equipped with female connectors in which all functional boards are inserted. It carries the system buses. *See also* backplane.

mother crystal—The quartz crystal found in nature. It has the characteristic geometric design of a crystal (i.e., flat faces at definite angles to each other), but all or some of the faces may be worn because of abrasion with stones or other objects.

motional feedback—Correction of a speaker's response by feeding information about its motion back to the amplifier. The amplifier then compares the speaker's motions with its own output and changes this output so as to counteract any changes (distortions) created by the speaker. Such speakers usually have special servo amplifiers built in, though a few can be used with other amplifiers if these are modified.

motional impedance—Also called loaded motional impedance. The complex remainder after the blocked impedance of a transducer has been subtracted from the loaded impedance.

motion detector—A device used in security systems that reacts to any movement on a CCTV monitor by automatically setting off an alarm when the monitor is not manned.

motion frequency—1. The natural frequency of a servo system. 2. The frequency at which a given servo tends to oscillate.

motion-picture pickup—A television camera or technique for televising scenes directly from motion-picture film.

motion-sensing—A type of tape transport in which certain actions that could break or spill the tape are prevented or delayed until the instant the tape has come to a stop or reached a speed that allows the action to take place safely.

motion sensor—A sensor that responds to the motion of an intruder. *See also* infrared motion detector; radio-frequency motion detector; sonic motion detector; ultrasonic motion detector.

motor—1. A device that moves an object. Specifically, a machine that converts electric energy into mechanical energy. 2. A device that converts continuous electric current into a regular rotary motion.

Motor.

motor board—Also called tape-transport mechanism. The platform or assembly of a tape recorder on which the motor (or motors), reels, heads, and controls are mounted. It includes parts of the recorder other than the amplifier, preamplifier, speaker, and case.

motorboating—1. Interference heard as the characteristic “putt-putt” made by a motorboat. It is due to self-oscillation, usually pulsating, in an amplifier below or at a low audio frequency. 2. A generally periodic, relatively low-frequency pulse disturbance of the output voltage of a regulated power supply, frequently line- or load-dependent, unstable, and significantly large, as in the case of oscillations.

motor circuit switch—See disconnect switch.

motor controller—A device or group of devices that serves to govern, in a predetermined manner, the electrical power delivered to a motor.

motor converter—A device for converting an alternating current to a pulsating direct current. It consists of an induction motor to which an ac supply is connected. The armature of the induction motor is linked mechanically to the armature of a synchronous converter, which is connected to a dc circuit.

motor-driven relay—A relay in which the contacts are actuated by the rotation of a motor shaft.

motor effect—The repulsion force exerted between adjacent conductors carrying currents in the opposite direction.

motor element—That portion of an electroacoustic receiver that converts energy from the electrical system into mechanical energy.

motor-field control—The method of controlling the speed of a motor by changing the magnitude of its field current.

motor field-failure relay—Also called field loss relay. A relay that functions to disconnect the motor armature from the line in the event of loss of field excitation.

motor field induction heater—An induction heater in which the inducing winding typifies that of a rotary or linear induction motor.

motor-generator set—A motor-generator combination for converting one kind of electric power to another (e.g., alternating current to direct current). The two are mounted on a common base and their shafts are coupled together

motorized lens—A camera lens fitted with a small electric motor that can focus the lens, open the diaphragm, or, in the case of a zoom lens, change the focal length, all by remote control.

motor junction (conduit) box—An enclosure on a motor for the purpose of terminating a conduit run and joining the motor to power conductors.

motor lead wire—Wire that connects to the usually fragile and easily damaged magnet wire found in coils, transformers, and stator or field windings. General requirements are abrasion resistance, toughness, flexibility, dielectric strength, thermal resistance, and low percentage of extractables (where applicable, such as in hermetic wires).

motor meter—A meter comprising a rotor, one or more stators, and a retarding element that makes the speed of the rotor proportionate to the quantity being measured (e.g., power or current). A register, connected to the rotor by suitable gearing, counts the revolutions of the rotor in terms of the total.

motor-operated sequence switch—A multi-contact switch that fixes the operating sequence (or the major devices) during starting and stopping, or during other sequential switching operations.

motor-run capacitor—A capacitor that is left in the auxiliary motor winding, and which is in parallel with the main winding to obtain a higher power factor and efficiency.

motor-start capacitor—A capacitor that is in the circuit only during the starting period of a motor. The capacitor and its auxiliary winding are disconnected automatically by a centrifugal switch or other device when the motor reaches a predetermined speed, after which the motor runs as an induction motor.

motor starter—A device arranged to start an electric motor and accelerate it to normal speed; a motor starter has no running position other than fully on. It is a combination of all the switching means required to start and stop the motor, and it incorporates suitable overload protection.

mount—The flange or other means by which a switching tube, or a tube and cavity, are connected to a waveguide.

mount structure—The essential elements of a vacuum tube except the envelope.

mouse—A cigarette-pack-size hemispherical or rectangular input device moved with one hand on a horizontal surface that causes corresponding movements of a cursor on a computer's monitor. A mouse will usually have one or more finger-operated switches so that it can generate both on-off and positional input. The mouse may be connected to the computer by a cord or it may be wireless.

mousepad—A pad used under a mouse to provide more traction for the mouse ball.

mouth of a horn—The end having the larger cross section.

M-out-of-N code—A type of fixed-binary code in which M of the N digits are always in the same state.

MOV—Abbreviation for metal-oxide varistor. A varistor having a sintered zinc-oxide element and a symmetrical voltage-current characteristic. Such devices provide bidirectional transient suppression capability, enabling them to protect circuits against transient overvoltage occurring from opposite directions. These devices absorb very large amounts of energy—up to 10 K joules.

movable contact—The one of a pair of contacts that is moved directly by the actuating system.

movement differential—The distance or angle from the operating position to the releasing position of a momentary contact switch.

move mode—In some variable-word-length computers, data transmission in which certain delimiters are not moved with the data (as opposed to load mode).

moving average—An arithmetic average of the n most recent observations. As each new observation is added, the oldest one is dropped. The value of n , the number of periods to use for the average, reflects responsiveness versus stability in the same way that

the choice of smoothing constant does in exponential smoothing.

moving-coil galvanometer—A galvanometer in which the moving element is a suspended or pivoted coil.

moving-coil meter—A meter in which a coil pivots between permanent magnets.

moving-coil microphone—Also called a dynamic microphone. 1. A moving-conductor microphone in which the diaphragm is attached to a coil positioned in a fixed magnetic field. The sound waves strike the diaphragm, moving it, and hence the coil, back and forth. An audio-frequency current is induced in the moving coil in the magnetic field and coupled to the amplifier. 2. A microphone using a permanent magnet and a vibrating coil or ribbon as its transducing system.

Moving-coil microphone.

moving-coil pickup—Also called dynamic pickup or reproducer. 1. A phonograph pickup in which a conductor or coil produces an electric output as it moves back and forth in a magnetic field. 2. A type of magnetic cartridge in which the coils, connected to the stylus, move within a stationary magnetic field. Output from such cartridges is low, and the stylus cannot usually be replaced by the user, but some users feel the sound quality outweighs these inconveniences.

Moving-coil pickup.

moving-coil speaker—Also called a dynamic speaker. A speaker in which the moving diaphragm is attached to a coil, which is conductively connected to the source of electric energy and placed in a constant magnetic field. The current through the coil interacts with the

magnetic field, causing the coil and diaphragm to move back and forth in step with the current variations through the coil.

moving-conductor microphone—A microphone that produces its electric output from the motion of a conductor in a magnetic field.

moving-conductor speaker—A speaker in which a conductor is moved back and forth in a steady magnetic field. The cone is moved by the reaction between the magnetic field and the current in the conductor.

moving contact—The portion of a relay or switch that moves toward or away from a fixed contact.

moving element—The portion of an instrument that moves as a direct result of a variation in the electrical quantity being measured by the instrument. One-half the weight of the springs (when used) is included in the weight of the moving element.

moving-head disk—An economical disk drive using a single head to access all the tracks.

moving-iron instrument—An instrument in which the current in one or more fixed coils acts on one or more pieces of soft iron or magnetically similar material, at least one of which is movable. The various forms of this instrument (plunger, vane, repulsion, attraction, repulsion-attraction) are distinguished chiefly by their mechanical construction. Otherwise, the action is the same.

moving-magnet instrument—An instrument in which a movable permanent magnet aligns itself in the field produced by another permanent magnet and an adjacent coil or coils carrying current, or by two or more current-carrying coils.

moving-magnet magnetometer—A magnetometer in which the torques act on one or more permanent magnets, which can turn in the field to be measured. Some types use auxiliary magnets (gaussian magnetometer); others use electric coils (sine or tangent galvanometer).

moving-target indicator—Abbreviated MTI. A device that limits the display of radar information primarily to moving targets.

moving-vane meter—See magnetic-vane meter.

moving-vane movement—Also known as moving-iron movement. A meter movement consisting of fixed and movable iron vanes, surrounded by a field coil. A magnetic field produced by current in the field coil causes repulsion between the two vanes. Deflection of the movable vane is proportional to the current.

MPC—Abbreviation for multimedia personal computer. Any workable combination of multimedia technologies.

MPU—Abbreviation for microprocessor unit.

MPX filter—Abbreviation for multiplex filter. 1. A circuit to remove 19-kHz tones from a signal to be recorded, in order to prevent audible interference between a tape recorder's bias signal and the 19-kHz pilot tone in the output signal from a stereo FM tuner or receiver. Some receivers and tuners have such filters built in. 2. A circuit that removes 19-kHz fm pilot tones from a signal.

MRN—Abbreviation for minimum reject number.

mR/min—Abbreviation for milliroentgens per minute.

ms—Letter symbol for millisecond.

MSB—Abbreviation for most significant bit.

M-scan—Also called M-display. An A-scan radar display in which the target distance is determined by moving a pedestal signal along the base line until it coincides with the horizontal position of the target-signal deflection. The control that moves the pedestal is calibrated in distance.

MSD—Abbreviation for most significant digit.

MS-DOS—Abbreviation for Microsoft Disk Operating System. The operating system for the IBM PC and compatible personal computers.

msec—Abbreviation for millisecond.

MSI—Abbreviation for medium-scale integration. A term generally applied to integrated circuit chips containing 10 or more gate equivalents, but less than 100. Also applies to memory devices with fewer than 1 K (1024) bits of memory.

MSI- or LSI-component processor—A processing unit built around medium-scale and/or large-scale integrated circuits, as opposed to one built around a monolithic processor, such as a microprocessor.

MSS—Abbreviation for mobile-satellite service. A service that links mobile earth stations with base stations and with one another via one or more satellites.

M-S stereo system—See *mitte-seite* stereo system.

MT—Also called MTST. The IBM magnetic tape Electric typewriter.

MTBF—Abbreviation for mean time between failures.

MTE—Abbreviation for miles to empty. An electronic digital dashboard readout that indicates the number of miles to drive before the gas tank is empty (Ford Motor).

MTI—Abbreviation for moving-target indicator.

MTNS—Abbreviation for metal-thick-nitride semiconductor.

MTOS—Abbreviation for metal-thick-oxide semiconductor.

MTS—Abbreviation for message telecommunications service. 1. Services available to the public over the nationwide switched network. An interstate call is one example. 2. The official name for long-distance or toll service.

MTTF—Abbreviation for mean time to failure.

MTFF—Abbreviation for mean time to first failure.

MTR—Abbreviation for mean time to repair. Average time to repair a failure under the operating conditions encountered.

M-type backward-wave oscillator—A cross-field injected-beam oscillator. The electrons in this device interact with an rf wave traveling backward or opposite to the electron beam. It is efficient, broadband, and can be voltage-tuned. It is also insensitive to load variations.

mu—English spelling for the Greek letter μ .

μ —Greek letter mu. 1. Symbol for amplification factor. 2. Symbol for permeability. 3. Letter symbol for the prefix micro- (10^{-6})

μ A—Letter symbol for microampere.

mu-circuit—In a feedback amplifier, the circuit that amplifies the vector sum of the input signal and the feedback portion of the output signal in order to generate the output signal.

MUF—Abbreviation for maximum usable frequency.

mu-factor—Ratio of the changes between two electrode voltages, assuming the current and all other electrode voltages are maintained constant—i.e., it is a measure of the relative effect that the voltages on two electrodes have on the current in the circuit of a specified electrode.

μ H—Letter symbol for microhenry.

muldem—Acronym for *multiplexer/demultiplexer*.

Muller tube—A thermionic vacuum tube having an auxiliary cathode or grid connected internally to the main cathode through a high-value resistor.

multiaddress—Pertaining to computer instructions that specify two or more addresses.

multianode microchannel array detector—A photon-counting array for use in both space-borne and

ground-based photometric and spectroscopic instrumentation. The resulting tubes use opaque photocathodes, feedback-free microchannel plates, proximity-focused multianode readout arrays, and multilayer ceramic headers.

multianode tank—See multianode tube.

multianode tube—Also called multianode tank. An electron tube having two or more main anodes and a single cathode.

multiaperture reluctance switch—A two-aperture ferrite storage core that may be used to provide a nondestructive-readout memory for a computer.

multiband antenna—An antenna usable at more than one frequency band.

multicasting—Broadcasting a stereo program by using two FM stations. Two FM receivers are required.

multicavity magnetron—A magnetron in which the circuit has more than one cavity.

multicellular horn—A cluster of horns with juxtaposed mouths lying in a common surface. The cluster controls the directional pattern of the radiated energy.

multichannel radio transmitter—A radio transmitter having two or more complete radio-frequency portions capable of operating on different frequencies, either individually or simultaneously.

multichannel R/C—A radio-control installation that employs tuned reeds to supply several control functions. The basic carrier frequency remains the same, but different tones make possible a number of control channels.

multichannel sound—A system of stereo sound transmission for TV applications. Approved in early 1984 by the FCC, it is AM double-sideband for stereo L-R and operates on a 15,734-Hz pilot carrier, which is doubled to 31,468 Hz for stereo. Multichannel sound also contains higher-frequency carriers for SAP (second audio program) and professional channel(s).

multichip circuit—A microcircuit in which discrete, miniature active electronic elements (transistors and/or diode chips) and thin-film or diffused passive components or component clusters are interconnected by thermocompression bonds, alloying, soldering, welding, chemical deposition, or metallization.

multichip integrated circuit—1. An integrated circuit whose elements are formed on or within two or more semiconductor chips that are separately attached to a substrate. See also integrated circuit. 2. Hybrid integrated circuit that includes two or more SIC, MSI, or LSI chips. 3. An electronic circuit in which two or more semiconductor wafers that contain single elements or simple circuits are interconnected and encapsulated in a single package to give a more complex circuit.

multichip microcircuit—A microcircuit whose elements are formed on or within two or more semiconductor chips that are attached separately to a substrate.

multiconductor—More than one conductor within a single cable complex.

multicoupler—A device for connecting several receivers to one antenna and properly matching their impedances.

multidrop—A telephone line configuration in which a single transmission facility is shared by several end stations.

multidrop line—Also called a multipoint line. 1. A communication system configuration using a single channel or line to serve multiple terminals. Use of this type of line normally requires some kind of polling mechanism, addressing each terminal with a unique identification. 2. A communication line with several subsidiary controllers sharing time on the line under a central site's control.

multielectrode tube—An electron tube containing more than three electrodes associated with a single electron stream.

multielement parasitic array—An antenna consisting of driven dipoles and parasitic elements arranged to produce a highly directive beam.

multiemitter transistor—A transistor that has more than one emitter. Used mainly in logic circuits.

multifiber (fiber optic)—A coherent bundle of fused single fibers that behaves mechanically as a single glass fiber.

multifrequency tones—Telecommunication signaling code utilizing pairs of frequencies in the 700- to 1700-Hz range.

multifrequency transmitter—A radio transmitter capable of operating on two or more selectable frequencies, one at a time, using preset adjustments of a single radio-frequency portion.

multifunction—Pertaining to an integrated device containing two or more circuits integral to a single silicon chip. In addition, each circuit has all inputs and outputs available at terminals for testing and interconnection with other packages. Typical multifunction devices are quadruple gates and dual flip-flops.

multifunction array radar—An electronic scanning radar that will perform target detection and identification, tracking, discrimination, and some interceptor missile tracking on a large number of targets simultaneously and as a single unit.

multigun tube—A cathode-ray tube having more than one electron gun. Used in color television receivers and multiple-presentation oscilloscopes.

multihop propagation—The bouncing of radio waves from the ionosphere to increase their range.

multilayer—A type of printed-circuit board that has several layers of circuit etch or pattern, one over the other and interconnected by electroplated holes. Since these holes can also receive component leads, a given component lead can connect to several circuit points, reducing the required dimensions of a printed circuit board.

multilayer board—A high-density printed-wiring board that consists of alternating conductive pattern layers and insulating layers bonded together. Interlayer connections are included as required by means of plate-through holes.

multilayer ceramic capacitor—A miniature ceramic capacitor manufactured by paralleling several thin layers of ceramic. The assembly is fired after the individual layers have been electroded and assembled.

multilayer circuit—1. Three or more conductive patterns interspersed with layers of insulating base and laminated into sandwiches, with interconnection between layers provided by plate-through holes. 2. A composite circuit consisting of alternate layers of conductive circuitry and insulating materials (ceramic or dielectric compositions) bonded together with the conductive layers interconnected as required.

multilayer dielectric—A compound including glass and ceramic that is applied as an insulating barrier between conductors for multilayer and crossover work.

multilayer interconnection pattern—A technique used for the interconnection of arrays performing large, complicated electronic functions. This technique involves the use of alternating films of insulating and conducting materials as a precondition for the realization of multiple interconnection planes.

multilayer metallization—Abbreviated MLM. 1. A method used to increase the component density of a particular monolithic integrated circuit. Two or more

layers of interconnecting metallization are stacked on top of the chip; the layers are separated by a thin dielectric (insulating) film except at the desired contact points. 2. An integrated circuit fabricating technique that makes economically feasible more complex monolithic logic subsystems or arrays: LSI MLM permits signal paths to be routed most efficiently and to cross without interaction. As a result, integrated circuit chips can be smaller or can contain more circuitry.

multilayer printed circuit—A type of printed circuitry wherein 2 to 14 or more printed circuit layers are fabricated as a complete assembly.

multilayer substrates—Substrates that have buried conductors so that complex circuitry can be handled. Assembled using processes similar to those used in multilayer ceramic capacitors.

multileaving—A technique for allowing simultaneous use of a communications line by two or more terminals.

multimedia or multi-media—1. Term used to describe the use of more than one medium in a program or system, such as the use of audio, video, graphics, animation, and computer data together for a program. Video had been considered separate from audio and computers separate from video and audio. Multimedia means the joining of any two or more of these. Multimedia computers play back high-quality sound and video, as well as text and graphics. Multimedia combines multiple forms of media in the communication of information between users and machines. 2. The presentation of information on a computer using video, audio, animation, and graphics technologies combined in one interactive package.

multimedia communications—Communication that is made up of a combination of text, graphics, video, and audio.

multimeter—1. Electronic device for measuring resistance and ac or dc current and voltage. *See also* circuit analyzer. 2. A portable test instrument that can be used to measure voltage, current, and resistance. 3. A meter having multiple scales. Usually means a volt-ohm-milliammeter.

multimode fiber—1. An optical fiber that supports propagation of more than one mode of a given wavelength. 2. An optical fiber that propagates optical energy in more than one mode. 3. An optical fiber that transmits many modes.

multimode operation—The operation of a laser sufficiently above threshold so as to stimulate more than one mode. If the modes are not degenerate, the output pattern will contain measurable power at more than one frequency.

multimoding—The simultaneous generation of many frequencies instead of one discrete frequency.

multioffice exchange—A telephone exchange area in which there are several central office units.

multiplier—A high-power, high-speed microwave switching device in which an rf electric field drives a thin cloud of electrons back and forth between two parallel plane surfaces located in a vacuum. The device can be used as a switch in a waveguide or for high-speed switching of pulses in other microwave systems.

multi-pass sort—A computer program for sorting more data than can be contained by the internal computer storage. Intermediate storage, such as disk, tape, or drum, is required.

multipath—1. The constructive and destructive combination of two or more out-of-phase versions of an FM signal at the receiver. It occurs when a building or similar structure reflects a portion of the signal. When the reflected signal arrives at the receiving antenna, its phase slightly lags the phase of the signal traveling directly

from the transmitting site to the receiving antenna. 2. A condition in which a signal reaches the receiving antenna over two or more paths of different lengths. The resulting interference causes distortion in the receiver, as well as loss of stereo channel separation. Multipath distortion can be minimized by using a directional receiving antenna, and by tuners having a low capture ratio and high AM suppression. Some tuners also have visual or audible multipath indicators that can be used as aids in adjusting the antenna for minimum multipath interference.

multipath cancellation—In effect, complete cancellation of signals because of the relative amplitude and phase differences of the components arriving over separate paths.

multipath delay—A form of phase distortion occurring most often in high-frequency layer-refracted or reflected signals, and also in VHF scattered signals. The existence of more than one signal path between transmitter and receiver causes the signal components to reach the receiver at slightly different times, causing echoes or ghosting.

multipath distortion/reception—Owing to reflection of the VHF FM signal by large buildings, hills, etc., a receiver sometimes receives not only the direct signal but also a reflected signal slightly later due to the greater path distance traveled. This results in high-order harmonic distortion and impairment to the stereo separation and quality.

multipath effect—The arrival of radio waves at slightly different times because all components do not travel the same distance.

multipath propagation—A transmission path anomaly that acts as a time-varying source of signal nonlinearity. Multipath propagation can distort or reduce a received signal to the point of unreliable reception. In television, multipath transmission is manifested as image ghosting.

multipath reception—Reception in which the radio signal from the transmitter travels to a receiver antenna by more than one route, usually because it is reflected from obstacles. The result is seen as ghosts in a TV picture.

multipath transmission—The phenomenon whereby signals reach the receiving antenna from two or more paths and usually have both amplitude and phase differences. It may cause jitter in facsimile (in Europe it is called echo).

multipattern microphone—A microphone that can be switch selected to provide two or more pickup patterns.

multiphonic organ—An electronic musical instrument in which there are only as many generators as notes you wish to play at the same time, as distinct from one generator for every note on the keyboard, which is the case with a polyphonic organ.

multiple—1. A group of terminals arranged in parallel to make a circuit or group of circuits accessible at any of several points to which a connection can be made. 2. To render a circuit accessible as in (1) above by connecting it in parallel with several terminals.

multiple access—1. The use of a communication satellite by more than one pair of ground stations at a time. Ideally it lets many independent ground stations use an active repeater without interfering with each other. 2. Pertaining to a computer system in which a number of online communication channels provide concurrent access to the common system.

multiple accumulating registers—In a computer, additional internal storage capacity that can contain loading, storing, adding, subtracting, and comparing factors up to four computer words in length.

multiple-address code—A computer instruction code that includes more than one address.

multiple-address instruction—In a computer, an instruction that contains more than one address.

multiple-aperture core—A magnetic core that has two or more holes through which may be passed wires and around which there may be magnetic flux. Such cores may be used for nondestructive reading.

multiple array—Two or more antennas mounted on the same mast with outputs coupled together. Multiple arrays are used to increase gain and directivity.

multiple-beam laser—A laser having a Q-switching method that allows separate parallel volumes of the lasing material to act independently of each other. This way, it is capable of producing several separate beams and is useful in high-speed holographic technology.

multiple break—In an electrical circuit, an interruption at more than one point.

multiple-break contacts—A contact arrangement such that a circuit is opened in two or more places.

multiple-chip circuit—See hybrid integrated circuit.

multiple-circuit layout—Layout of an array of individual circuits on a substrate.

multiple-conductor cable—A combination of two or more conductors cabled together and insulated from one another and from sheath or armor where used. Special cables are referred to as three-conductor cable, seven-conductor cable, fifty-conductor cable, etc.

multiple-conductor concentric cable—A cable composed of an insulated central conductor with one or more tubular stranded conductors laid over it concentrically and insulated from one another.

multiple-contact switch—A switch in which the movable contact can be set to any one of several fixed contacts.

multiple course—One of a number of lines of position defined by a navigational system. Any one of these lines may be selected as a course line.

multiple jacks—A series of jacks that appear on different panels and that have their tips, rings, and sleeves, respectively, connected in parallel.

multiple-length number—In a computer, a quantity or expression that occupies two or more registers.

multiple modulation—Also called compound modulation. A succession of modulation processes in which the modulated wave from one process becomes the modulating wave for the next.

multiple pileup—Also called multiple stack. An arrangement of contact springs composed of two or more pileups.

multiple-precision notation—A technique whereby two or more computer words represent a single numeric quantity.

multiple processing—Configuring two or more processors in a single system, operating out of a common memory. This arrangement permits execution of as many programs as there are processors.

multiple programming—In computer programming, simultaneous execution of two or more arithmetical or logical operations.

multiple-purpose tester—A single test instrument having several ranges, for measuring voltage, current, and resistance.

multiple-reflection echoes—Returned echoes that have been reflected from an object in the radar beam. Such echoes give a false bearing and range.

multiple sound track—Two or more sound tracks printed side by side on the same medium, containing the

same or different material, but meant to be played at the same time (e.g., those used for stereophonic recording).

multiple stack—*See* multiple pileup.

multiple switchboard—A manual telephone switchboard in which each subscriber line is connected to two or more jacks so that they are within reach of more than one operator.

multiple tube counts—Spurious counts induced in a radiation counter by previous tube counts.

multiple-tuned antenna—A low-frequency antenna with one horizontal section and several tuned vertical sections.

multiple-twin quad—Quad cable in which the four conductors are arranged in two twisted pairs, and the two pairs are twisted together.

multiple-unit semiconductor device—A semiconductor device having two or more sets of electrodes associated with independent carrier systems. It is implied that the device has two or more output functions that are independently derived from separate inputs (e.g., a duotriode transistor).

multiple-unit steerable antenna—Abbreviated MUSA. An antenna unit composed of a number of stationary antennas, the major composite lobe of which is electrically steerable..

multiple-unit tube—Also called a duodiode, duotriode, diode-pentode, duodiode-triode, duodiode-pentode and triode-pentode. An electron tube containing two or more groups of electrodes associated with independent electron streams within one envelope.

multiplex—Abbreviated mux. 1. To carry out several functions simultaneously in an independent but related manner. 2. To interleave or transmit two or more messages simultaneously on a single channel. 3. A technique for transmitting two or more signals at the same time on the same carrier frequency. *See* FM stereo. 4. Transmission of two or more channels on a single carrier so that they may be recovered independently by a tuner. In FM stereo, transmission of left-plus-right (sum) signal and left-minus-right (difference) signal on main carrier and subcarrier, respectively. The multiplex decoder in the tuner recovers independent left and right stereo channels from the multiplex signal. 5. To combine two or more electrical signals into a single, composite signal. This may be done on a frequency basis (frequency-division multiplexing) or on a time basis (time-division multiplexing). 6. The system used to transmit two stereo program channels on a single FM carrier in such a form that the complete program (left plus right channels) can be heard on a mono FM tuner. A multiplex demodulator in the tuner converts the composite received program to its two-channel form.

multiplex adapter—A circuit incorporated in an FM tuner or receiver to permit two-channel, or stereophonic, reception from a station transmitting multiplex broadcasts. The other audio channel is produced by demodulating the transmitted subcarrier.

multiplex code transmission—The simultaneous transmission of two or more code messages in either or both directions over the same transmission path.

multiplexed line—A data-communication line equipped with multiplexers at each end.

multiplexer—Abbreviated mux. 1. A device for accomplishing simultaneous transmission of two or more signals over a common transmission medium. 2. An analog or linear device for selecting one of a number of inputs and switching its information to the output; the output voltage follows the input voltage with a small error. 3. A digital device that can select one of a number of inputs and pass the logic level of that input-channel. Selection usually is presented to the device in binary weighted form

multiple stack — multiplex printing telegraphy

and decoded internally. The device acts as a single-pole multiposition switch that passes digital information in one direction only. 4. A device that will interleave (time division) or simultaneously transmit (frequency division) two or more messages on the same communications channel. 5. A device that uses several communication channels at the same time and transmits and receives messages and controls the communication lines. This device itself may or may not be a stored-program computer. 6. A device that can combine several low-speed inputs into one high-speed output. Multiplexers can also function in reverse, a process called demultiplexing. 7. A decision-making type of digital building block that routes data from its one input to any one of several outputs. 8. The device or technique used to share a resource (usually a memory or a bus). 9. In television, a specialized optical device that makes it possible to use a single television camera in conjunction with one or more motion-picture projectors and/or slide projectors in a film chain. The camera and projectors are in a fixed relationship, and prisms or special (dichroic) mirrors are used to provide smooth and instantaneous nonmechanical transition from one program source to the other. 10. A device for selecting a single signal from one of many sources (similar to a multiposition switch). 11. A hardware device that allows the transmission of a number of different signals simultaneously over a single channel. 12. A combination of hardware and software that allows simultaneous transmission and reception of two or more data streams on a single channel.

multiplex filter—*See* MPX filter.

multiplexing—Abbreviated mux. 1. A method of signaling characterized by the simultaneous and/or sequential transmission and reception of multiple signals over a communication channel with means for positively identifying each signal. The signaling may be accomplished over a wire path or radio carrier or combination of both. 2. The division of a transmission facility into two or more channels either by splitting the frequency band transmitted by the channel into narrower bands, each of which is used to constitute a distinct channel (frequency-division multiplexing) or by allotting this common channel to several different information channels, one at a time (time-division multiplexing). 3. Combining two or more channels onto one transmission facility. 4. The time-shared scanning of a number of data lines into a single channel. Only one data line is enabled at any instant. 5. The combination of two or more measurements for transmission along a single wire, path, or carrier. The combination of information signals for transmission on one channel. 6. The act of combining a number of individual message circuits for transmission over a common transmission path. 7. A technique for the concurrent transmission of two or more signals in either or both directions, over the same wire, carrier, or other communication channel. The two basic multiplexing techniques are time-division multiplexing and frequency-division multiplexing.

multiplex operation—Simultaneous transmission of two or more messages in either or both directions over the same transmission path.

multiplexor—A device used for division of a transmission facility into two or more subchannels, either by splitting the frequency band into narrower bands (frequency division) or by allotting a common channel to several different transmitting devices one at a time (time division).

multiplex printing telegraphy—The form of printing telegraphy that uses a line circuit to transmit one character (or one or more pulses of a character) for each of two or more independent channels.

multiplex radio transmission—The simultaneous transmission of two or more signals over a common carrier wave.

multiplex stereo—A system of broadcasting both channels to a stereo program on a single carrier. This is commonly done by modulating an ultrasonic subcarrier—either with the signals of one of the stereo channels, or by a different signal composed of the two channels combined out of phase, or subtractively.

multiplex telegraphy—Telegraphy employing multiplex code transmission.

multiplex transmission—The simultaneous transmission of two or more signals within a single channel. Multiplex transmission as applied to FM broadcast stations means the transmission of facsimile or other signals in addition to the regular broadcast signals.

multiple x-y recorder—A recorder that plots a number of independent charts simultaneously, each showing the relation of two variables, neither of which is time.

multiplication point—A mixing point whose output is obtained by multiplication of its inputs.

multiplier—1. A device in which the output represents the product of the magnitudes represented by the two or more input signals. 2. A series register placed in a voltmeter to increase the voltage range. 3. A fixed resistance, connected in series with the moving coil of a voltmeter, to enable measurements over a larger voltage range.

multiplier phototube—Also called photomultiplier. 1. Phototube with one or more dynodes between its photocathode and the output electrode. The electron stream from the photocathode is reflected off each dynode in turn, with secondary emission adding electrons to the stream at each reflection. 2. A tube consisting of an evacuated envelope with a photocathode that emits electrons when exposed to light. These electrons are accelerated by a positive electrostatic field and fall on a metal surface, where they emit secondary electrons that are again accelerated to generate more electrons at the next metal surface, and so on. The whole arrangement thus acts as a combination of a simple photocell with a high-gain amplifier in a self-contained unit.

multiplier-quotient register—In a computer, a register used for operations that involve multiplication and division.

multiplier resistor—See multiplier, 2.

multiplier traveling-wave photodiode—A device in which increased sensitivity is obtained by combining the construction of a traveling-wave tube with that of a multiplier phototube.

multiplier tube—A vacuum tube in which sequential secondary emission from a number of electrodes is used to obtain increased output current. The electron stream is reflected from the first electrode of the multiplier to the second, and so on.

multiplying factor—The number by which the reading of a meter must be multiplied to obtain the true value.

multiport—Describes a network configuration in which several transmission facilities connect several end stations to a master station.

multiport circuit—A circuit interconnecting several locations, wherein information transmitted is available at all locations simultaneously.

multiport line—See multidrop line.

multiport recorder—A data recorder that uses a single pen to record the values of several parameters by multiplexing of the inputs, that is, by sequentially switching the inputs so that one parameter is recorded for a brief period, than the next, and so forth. Since the curves may cross each other and make identification

of parameters a problem, various methods of identifying each trace have been developed.

multipolar—Having more than one pair of magnetic poles.

multiport—Refers to the capability of communications equipment to accept more than one input/output data line.

multiport relay—A relay having more than one operate or nonoperate position, e.g., a stepping relay.

multiprocessing—1. The simultaneous or interleaved execution of two or more programs or instruction sequences by a computer or computer network. It may be accomplished by multiprogramming, parallel processing, or both. 2. The operation of more than one processing unit within a single system. Separate processors may take over communications or peripheral control, e.g., while the main processor continues program execution. 3. A complex technique that permits more than one computer program to be executed simultaneously on more than one processor in a shorter period of time than is required for the overall sequentially organized task, for which time may not be available. 4. The operation of several CPUs or similar programmable processors operating relatively independently of one another but sharing common resources, such as memory and I/O, over a common multiple-processor bus. This arrangement is well suited for larger overall processing tasks for which one processor is not a cost-effective solution. In general, multiprocessing increases system reliability, improves the use of resources, and permits greater system performance. Through parallel action, it often multiplies system performance by the number of processors used. Multiprocessing permits system performance to greatly surpass that of a single CPU. 5. Two or more CPUs operating together either in a tightly coupled system, in which all I/O and memory share a parallel bus, and access is interleaved cycle by cycle, or in a loosely coupled system, in which CPUs have independent memory and I/Os and share parallel or serial bus links. 6. Independent and simultaneous processing accomplished by a computer configuration consisting of more than one arithmetic and logic unit, each being capable of accessing a common memory. 7. Computer operation in which two or more similar computers are hooked together. The individual computers can work on different parts of the same problem simultaneously, or on entirely different problems. Or each computer can specialize in a particular kind of task, or two computers can work on the same program and check each other. 8. The ability of an operating system to support multiple processors. Generally, in order to make the operating system task manageable, all processors are equivalent and interchangeable, although this is not a requirement. 9. A processing method in which program tasks are logically and/or functionally divided among a number of independent CPUs, with the programming tasks being simultaneously executed.

multiprocessor—1. A computer capable of executing one or more programs simultaneously using two or more processing units under integrated control of programs or devices. 2. A system architecture that permits complex operations, like computation, to be carried on simultaneously at different nodes.

multiprogramming—1. A method in which many programs are interleaved or overlapped so that they can be operated on within the same interval of time. This technique is the basis for time-shared operation. 2. A programming technique in which two or more programs are operated on a time-sharing basis, usually under control of a monitor that determines when execution of one program stops and another begins. 3. The technique of utilizing several interleaved programs concurrently in a single computer system. 4. Pertaining to the concurrent

execution of two or more programs by a computer. The programs operate in an interleaved manner within one computer system. 5. A mode of operation in which a computer divides its time among several programs, working on one for a while, then switching to another. 6. A word processing system that can simultaneously process different applications such as file sorting and text editing or even data-processing tasks. 7. Another term for multitasking.

multirate meter — A meter that registers at different rates or on different dials at different hours of the day.

multi-rf-channel transmitter — A radio transmitter having two or more complete radio-frequency portions that may be operated on different frequencies either individually or simultaneously.

multisegment magnetron — A magnetron with an anode divided into more than two segments, usually by parallel slots.

multispeed motor — A motor that can be operated at any one of two or more definite speeds, each practically independent of the load.

multistage LNA — Three or more transistor amplifier stages placed end to end (cascaded) so that the gain contribution of each will add up to total gain of approximately 50 dB. In most low-noise amplifiers (LNAs), the first stage (closest to the antenna feed probe) has the best noise characteristics needed to minimize the noise propagated along through the remaining stages.

multistage tube — An X-ray tube in which the cathode rays are accelerated by multiple ring-shaped anodes, each at a progressively higher potential.

multistate noise — Noise consisting of erratic switching that is generated within a device at various sharply defined levels of applied current.

multitasking — See also multiprogramming. 1. The capability of a personal computer to run more than one software program, or task, by interleaving segments of each task. 2. The concurrent execution of two or more tasks or applications by a computer. 3. A method of achieving concurrency by separating a program or programs into two or more interrelated tasks that share code, buffers, and files while running.

multithreading — The running of several processes in rapid sequence (multitasking) within a single computer program.

multitrack magnetic system — A magnetic recording system in which its medium has two or more tracks.

multitrack recording system — A recording system in which the medium has two or more recording paths, which may carry the same or different material but are played at the same time.

multiturn potentiometer — A potentiometer that must be rotated more than one turn for the slider to travel the complete length of the resistive element.

multiunit tube — An electron tube containing within one glass or metal envelope two or more groups of electrodes, each associated with separate electron streams.

multivibrator — A relaxation oscillator in which the in-phase feedback voltage is obtained from two electron tubes or transistors. Typically, their outputs are coupled through resistive-capacitive elements. The time constants of the coupling elements determine the fundamental frequency, which may be further controlled by an external voltage. When such a circuit is normally in a nonoscillating state and a trigger signal is required to start a cycle of operation, it is called a one-shot, flip-flop, or start-stop multivibrator.

Tube circuit.

FET circuit.

Multivibrator.

multivoltage control—A method of controlling the voltage of an armature by successive impression of a number of substantially fixed voltages on the armature. The voltages are usually obtained from multicommutator generators common to a group of motors.

multiwire—A machine-controlled process for placing a customized interconnection pattern of insulated wires on a prepared epoxy glass laminate substrate.

MUM—Abbreviation for methodology for unmanned manufacturing. A Japanese program established to develop an unmanned factory in the early 1980s. A facility that depends heavily on robots.

Mumetal—A metallic alloy with high permeability and a low hysteresis loss. It is excellent for magnetic shielding.

Mumetal shield—A cone-shaped covering made of Mumetal. Placed over the flared portion of a picture tube, it acts as a shield to prevent outside magnetic fields from affecting the alignment of the electron beams in the tube.

μmho —Letter symbol for micromho.

Munsell Book of Color—A collection of color samples arranged in charts according to equal visually spaced steps in Munsell hue, value, and chroma.

Munsell chroma—Numerical scale of chroma devised by A. H. Munsell and exhibited in the Munsell Book of Color.

Munsell color system—A system of surface-color specification based on perceptually uniform color scales for the three variables: Munsell hue, Munsell value, and Munsell chroma. For an observer of normal color vision, adapted to daylight, and viewing the specimen when illuminated by daylight and surrounded with a middle gray to white background, the Munsell hue, value, and chroma of the color correlate well with the hue, lightness, and saturation of the perceived color.

Munsell notation—Numerical-alphabetical description of color according to Munsell hue, value, and chroma.

Munsell system—A color-specification system used principally in photography and color printing. It is based on sample cards containing the hue scale in five principal and five intermediate hues, and the brilliance scale in ten steps ranging from black to white. These represent visual, not physical, intervals.

Munsell value—1. In the Munsell system of object color specification, the dimension that indicates the apparent luminous transmittance or reflectance of the object on a scale having approximately equal perceptual steps under the usual conditions of observation. 2. Numerical scale of lightness devised by A. H. Munsell and exhibited in the Munsell Book of Color.

$\mu\Omega$ —Letter symbol for micro-ohm.

Murray loop test—A method of localizing a fault in a cable. This is done by replacing two arms of a Wheatstone bridge with a loop formed by the cable under test and a good cable connected to the far end of the defective cable.

μs —Letter symbol for microsecond.

MUSA antenna—Acronym for multiple-unit steerable antenna.

muscle chip—An interface circuit that has high-voltage and/or high-current capability to drive relays displays, motors, printers, lamps, etc., from inputs provided from logic or other low-power signal sources (Sprague Electric Co.).

mush winding—A type of winding in an ac machine. The conductors are placed one by one in prepared slots and the end connections are separately insulated.

musical cushion—A musical selection added at the end of a program that is running short or over. By playing

it slowly or cutting out portions, the program director can make the program come out on time.

musical echo—See flutter echo, 2.

musical instrument digital interface—See MIDI.

musical quality—See timbre.

music power—Also called dynamic power. 1. The short-term power available from an amplifier for the reproduction of program material. The music power output exceeds the rms power rating to a greater or lesser extent. Its measurement is standardized by the Institute of High Fidelity (IHF) and represents a practical means of stating the actual capabilities of an amplifier for the reproduction of program material. 2. The power that an amplifier (with both channels working, when stereo) is capable of delivering on a music type signal. Output is rated in watts into a specified load value, and the test signal is sometimes an interrupted sine-wave signal (i.e., tone bursts). This method of power expression fails to take account of the power supply impedance and regulation and the efficiency of the power transistor heat sinks. The power obtained is always greater than that measured when the test signal is continuous wave (i.e., steady-state sine-wave signal) and with both channels driven together. 3. A measurement of the peak output power capability of an amplifier performed either with a signal duration sufficiently short that the amplifier power supply does not sag during the measurement or with high-quality external power supplies. This measurement (an IHF standard) assumes that with normal music program material the amplifier power supplies will sag insignificantly.

must-operate value—A specified functioning value at which all relays meeting the specification must operate.

must-operate voltage—The minimum control voltage at which a relay will always turn on.

must-release value—The specified operating value at which all relays that meet a certain specification must release.

must-release voltage—The maximum control voltage at which a relay switches from on to off.

MUT—Abbreviation for module under test.

mute—To suppress the audio output of an amplifier in response to a command signal even though an input may be present. Used in stereo receivers to prevent the off-channel spurious response produced from reaching the speaker while tuning.

muting—Muffling or deadening a sound. See also quieting.

muting circuit—1. A circuit that cuts off the receiver output when the rf carrier reaching the first detector is at or below a predetermined intensity. 2. A circuit for making a receiver insensitive while its associated transmitter is on.

muting switch—A switch used with automatic tuning systems to silence the receiver while it is being tuned.

mutual capacitance—Capacitance between two conductors with all other conductors connected together and to a grounded shield. (Does not apply to a shielded single conductor.)

mutual conductance—See transconductance.

mutual-conductance meter—See transconductance meter.

mutual-conductance tube tester—See transconductance tube tester.

mutual exclusion—A process synchronization rule that prohibits more than one task from using the same resource at the same time.

mutual impedance—1. Between any two pairs of network terminals (all other terminals being open), the

ratio of the open-circuit potential at either one of the two pairs to the current applied to the other pair of network terminals. 2. The impedance existing between the primary and secondary of a transformer. Numerically equal to the secondary voltage divided by the primary current.

mutual inductance—The common inductance of two coupled electrical circuits that determines, for a given rate of change of current in one of the circuits, the electromotive force that will be induced in the other.

Mutual inductance.

mutual induction—The production of a voltage in one circuit by a changing current in a neighboring circuit, even though no apparent connection exists between the two circuits.

mutual inductor—An inductor for changing the mutual inductance between two circuits.

mutual information—*See* transinformation.

mutual inductance — myriametric waves

mutual interference—Human-made interference from two or more electrical or electronic systems that affects these systems on a reciprocal basis.

μV —Letter symbol for microvolt.

μW —Letter symbol for microwatt (10^{-6} watt).

mux—1. Abbreviation for multiplex. 2. Abbreviation for multiplexer. 3. Abbreviation for multiplexing.

MV—Letter symbol for megavolt.

mV—Letter symbol for millivolt.

MVA—Letter symbol for megavolt-ampere.

MW—Letter symbol for megawatt.

mW—Letter symbol for milliwatt.

MWh—Abbreviation for megawatthour.

Mycalex—Trade name of the Mycalex Corp. for mica bonded with glass. Mycalex has a low power factor at high temperatures, and it is a good insulator at all frequencies.

Mylar—Trade name of E. I. duPont de Nemours and Co., Inc., for a highly durable, transparent plastic film of outstanding strength. It is used as a base for magnetic tape and as a dielectric in capacitors.

Mylar capacitor—A capacitor in which Mylar film, either alone or in combination with another film or paper, is the dielectric.

myocardial electrodes—*See* implantable pacemaker.

myoelectric signals—Complex pulse potentials of 10 to 1000 microvolts with durations between 1 and 10 milliseconds as generated by a muscular effort, recorded from the body surface.

myograph—A recorder of forces of muscular contraction. *See also* electromyograph.

myokinesimeter—An apparatus for measuring the response of a muscle to stimulation by electric current.

myophone—An instrument for making audible the sound of a muscle when it is contracting.

myriametric waves—Very-low frequency band; 3 kHz to 30 kHz (100 km to 10 km).

N

n—Letter symbol for the prefix nano- (10^{-9}).

N—Symbol for number of turns, or the north-seeking pole of a magnet.

NA—Abbreviation for numerical aperture.

nA—Letter symbol for nanoampere.

NAB—Abbreviation for National Association of Broadcasters.

NAB curve—Also called NAB equalization. 1. The standard playback equalization curve set by the National Association of Broadcasters. 2. In tape recording, this is used to describe anything for which standards have been established by the National Association of Broadcasters to ensure complete interchangeability from one recorder to another of the same speed.

NAB reel, NAB hub—Reels and hubs used in professional recording, having a large center hole and usually an outer diameter of $10\frac{1}{2}$ inches (26.7 cm).

NAEB—Abbreviation for National Association of Education Broadcasters.

nail-head bond—An alternate term for ball bond.

nail heading—The flared condition of copper on the inner conductor layers of a multilayer board caused by hole drilling.

NAND—A function of A and B that is true if either A or B is false.

NAND circuit—1. A circuit in which the normal output of an AND circuit is inverted; a NOT-AND circuit. 2. A circuit that has its output in the logical 0 state if and only if all of the control (input) signals assume the logical 1 state.

NAND gate—1. A combination of a NOT function and an AND function in a binary circuit that has two or more inputs and one output. The output is logical 0 only if all inputs are logical 1; it is logical 1 if any input is logical 0. With logic of the opposite polarity, this type of gate becomes a NOR gate. 2. A multiple-control device that evidences the simultaneous appearance of all positive-pressure control signals with a single zero-output signal. With the loss of one or more control signals, the zero NAND output signal ceases. The NAND gate can also be defined as a complemented AND or NOT AND device. 3. An AND circuit that delivers an inverted output signal.

nano-—Prefix meaning one-billionth (10^{-9}). Letter symbol: n.

nanoampere—One-thousandth of a microampere (10^{-9} ampere). Letter symbol: nA

nanocircuit—An integrated microelectronic circuit in which each component is fabricated on a separate chip or substrate so that independent optimization for performance can be achieved.

nanofarad—One-billionth of a farad, equal to 10^{-9} farad, 0.001 microfarad, or 1000 picofarads. Letter symbol: nF.

High-speed TTL.

Standard TTL.

NAND gates.

nanohenry—One-thousandth of a microhenry, equal to 10^{-9} henry or 1000 picohenrys. Letter symbol: nH.

nanometer—A unit of length in the metric system equal to 10^{-9} meter. Formerly called a millimicron. Letter symbol: nm.

nanosecond—One-billionth of a second (10^{-9} second). Light travels approximately 1 foot (30.5 cm) in 1 nanosecond. Letter symbol: ns.

nanovolt—One-thousandth of a microvolt (10^{-9} volt). Letter symbol: nV.

nanovoltmeter—A voltmeter sufficiently sensitive to give readings in thousandths of microvolts.

Naperian logarithm—Also called hyperbolic or natural logarithm. A logarithm to the base 2.7128.

napiér—See neper.

narrow band—1. A band whose width is greater than 1 percent of the center frequency and less than one-third octave. 2. Pertaining to a communication channel of less than voice grade.

narrow-band amplifier—An amplifier designed for optimum operation over a narrow band of frequencies.

narrow-band axis—In phasor representation of the chrominance signal, the direction of the coarse-chrominance primary of a color TV system.

narrow-band FM—See narrow-band frequency modulation.

narrow-band FM adapter—An attachment that converts an AM communications receiver to FM.

narrow-band frequency modulation—Abbreviated NBFM. Frequency modulation that occupies only a small portion of the conventional FM bandwidth. Used mainly for two-way voice communication by police, fire, taxicabs, and amateurs.

narrow-band interference—Sharply tunable interference, having a spectrum that is small compared with the bandwidth of the measuring instrument. (Sine-wave carriers both modulated and unmodulated are good examples.)

narrow-sector recorder—A radio direction finder with which atmospheric waves are received from a limited sector related to the position of the antenna. The antenna is usually rotated continuously, and the bearing of the atmospheric waves recorded automatically.

NARTB—Abbreviation for National Association of Radio and Television Broadcasters, the former name of the National Association of Broadcasters.

***n*-ary code**—A code in which each element can be any one of *n* distinct kinds or values.

***n*-ary pulse-code modulation**—A type of pulse-code modulation in which the code for each element of information can consist of any one of *n* distinct kinds or values.

NASA—Acronym for National Aeronautics and Space Administration. The federal agency charged with all scientific space missions.

National Association of Broadcasters—Abbreviated NAB. The official association of the radio and television broadcasting industry. Formerly called the NARTB.

National Association of Radio and Television Broadcasters—Abbreviated NARTB. A name used for a number of years by an association of broadcasters. In 1958 the name was changed back to National Association of Broadcasters, an earlier title.

National Electrical Code—Abbreviated NEC. 1. A recognized authority on safe electrical wiring. The code is used as a standard by federal, state, and local governments in establishing their own laws, ordinances, and codes on wiring specifications. 2. A set of regulations governing construction and installation of electrical wiring and apparatus, established by the National Fire Protection Association and suitable for mandatory application by governmental bodies exercising legal jurisdiction. It is widely used by state and local authorities within the United States and is incorporated in OSHA regulations. It has the force of law only when enforced by municipalities or states. 3. A compendium of articles pertaining to the general electrical wiring field, containing provisions considered essential for the practical safeguarding of persons and property from hazards arising from the use of electricity.

National Electrical Manufacturers Association—Abbreviated NEMA. 1. An organization of

manufacturers of electrical products. 2. An industry association that standardizes specifications for cables, wires, and electrical components.

National Electrical Safety Code—A set of safety rules for the installation and maintenance of electric supply and communication lines, published as *National Bureau of Standards Handbook* and approved by the American Standards Association. It has the force of law only if enforced by municipalities or states.

national paging—Paging service provided on a national or regional basis, in which subscribers use a single pager that can operate in many different areas. This is usually achieved with a single frequency available nationwide (called nationwide paging) or through a form of networking that uses a pager that receives different frequencies in different areas.

National Television System Committee—Abbreviated NTSC. A committee organized in 1940 and comprising all United States companies and organizations interested in television. Between 1940 and 1941, it formulated the black and white television standards; between 1950 and 1953, it formulated the color television standards that were approved by the Federal Communications Commission.

nationwide paging—Method of national or regional paging in where a single frequency is used throughout the nation (or region) for sending messages to a paging system subscriber.

natural antenna frequency—The lowest resonant frequency of an antenna operated without external inductance or capacitance.

natural binary—1. A number system to the base 2, in which the 1s and 0s have weighted value in accordance with their relative position in the binary word. Carries may affect many digits. (Contrasted with Gray code, which permits only one digit to change state.) 2. The usual $2n$ code with 2, 4, 8, 16, . . . , $2n$ progression. An input or output high, or 1, is considered a signal, whereas a 0 is considered an absence of signal. This is a positive-true binary signal. Zero scale is then all 0s, while full scale is all 1s.

natural frequency—1. The frequency at which a system with a single degree of freedom will oscillate from the rest position when displaced by a transient force. Sometimes used synonymously with damped natural frequency. 2. The lowest resonant frequency of a circuit or component without adding inductance or capacitance.

natural frequency of an antenna—The lowest resonant frequency of an antenna with no added inductance or capacitance.

natural interference—Electromagnetic interference caused by natural terrestrial phenomena (atmospheric interference) or by natural disturbances outside of the atmosphere of the earth (galactic and solar noise).

natural logarithm—See Naperian logarithm.

natural magnet—Magnetic ore (e.g., a lodestone) that exhibits the property of magnetism in its natural state.

natural period—The period of the free oscillation of a body or system. When the period varies with amplitude, the natural period is the period when the amplitude approaches zero.

natural radiation—See background radiation.

natural resonance—See periodic resonance.

natural wavelength—The wavelength corresponding to the natural frequency of an antenna or circuit.

Navaglobe—A long-distance navigational system of the continuous-wave, low-frequency type. Bearing information is provided by amplitude comparison.

navaids — Navigational aids. The electronic facilities provided on or in the immediate vicinity of an airport so that a pilot using compatible airborne equipment can execute the instrument approach or approaches authorized for the airport.

navar — A coordinated series of radar navigation and traffic-control aids utilizing transmissions at wavelengths of 10 and 60 centimeters. In an aircraft, it provides distance and bearing from a given point, display of other aircraft in the vicinity, and commands from the ground. On the ground, it provides a display of all aircraft in the vicinity, as well as their altitudes and identities, plus means for transmitting certain commands.

navarho — A continuous-wave, low-frequency navigation system that provides simultaneous bearing and range information over long distances.

Navascreen — A system for the display and computation of air-traffic-control data based on information from radar and other sources.

navigation — The process of directing an airplane or ship toward its destination by determining its position, direction, etc.

navigational parameter — In a navigational aid, a visual or aural output having a specific relationship to navigational coordinates.

navigation beacon — A light, radio, or radar beacon that provides navigational aid to ships and aircraft.

NBFM — Abbreviation for narrow-band frequency modulation.

nc — 1. Abbreviation for normally closed. 2. Abbreviation for no connection.

NC — Abbreviation for numerical control.

nc contacts — Contacts that are normally closed when the control circuit is not energized.

n-channel — A device constructed on a p-type silicon substrate whose drain and source components are of n-type silicon.

n-channel FET — A field-effect transistor that has an n-type conduction channel.

n-channel MOS — 1. A metal-oxide semiconductor (unipolar) transistor in which the working current consists of negative (n) electrical charges. 2. A type of metal-oxide silicon field-effect transistor using electrons to conduct current in the semiconductor channel. The channel has a predominantly negative charge.

N-channel MOSFET.

n-conductor concentric cable — A cable composed of an insulated central conducting core with $n - 1$ tubular stranded conductors laid over it concentrically and separated by layers of insulation.

n-cube — Also called n -dimensional cube or n -variable cube. In switching theory, a term used to indicate two $n - 1$ cubes having corresponding points connected.

NC value — See noise-criteria value.

n-dimensional cube — See n -cube.

N-display — Also called N-scan or N-scope. A radar display similar to the K-display. The target appears as a pair of vertical deflections (blips) from the horizontal time base. Direction is indicated by the related amplitude of the vertical deflections. Target distance is determined by moving a pedestal signal (the control of which is calibrated in distance) along the base line until it coincides with the horizontal position of the vertical deflections.

near-end crosstalk — In a disturbed telephone channel, crosstalk propagated in the opposite direction from the current in the disturbing channel. The terminal in which the near-end crosstalk is present is ordinarily near, or coincides with, the energized terminal of the disturbing channel.

near field — 1. The acoustic radiation field close to the speaker or some other acoustic source. 2. The electromagnetic field within a distance of 1 wavelength from a transmitting antenna.

near infrared — 1. Name applied to the spectral region primarily comprising wavelengths between 3 and 30 meters. 2. That nonvisible radiant energy with wavelengths nearest the end of the visible spectrum.

near space — The space above the earth in which communication satellites travel, beginning at an altitude of about 120 miles (193 km).

near-ultraviolet — The longest wavelengths of the ultraviolet region, nominally 300 to 400 nanometers.

near zone — The region very close to a radio transmitting antenna in which the induction field predominates. The intensity of the induction field does not reduce in proportion to the square of the distance from the antenna.

NEC — Abbreviation for National Electrical Code. A consensus standard published by the National Fire Protection Association (NFPA) and incorporated in OSHA regulations.

necessary bandwidth — For a given class of emission, the minimum value of the occupied bandwidth sufficient to ensure the transmission of information at the rate and quality required for the system employed, under specified conditions. Emissions useful for the good functioning of the receiving equipment for example, the emission corresponding to the carrier of reduced carrier systems are included in the necessary bandwidth.

neck — The narrow tubular part of the envelope of a cathode-ray tube; it extends from the funnel to the base and houses the electron gun.

needle — 1. A probe used on stacks of punched cards. 2. See stylus, 1.

needle chatter — See needle talk.

needle drag — See stylus drag.

needle electrode — Small instrument used for subcutaneous electrical recording and stimulating.

needle gap — A spark gap having needlepoint electrodes.

needle pressure — See stylus force.

needle scratch — See surface noise.

needle talk — Audible sounds from a record player pickup in the vicinity of the stylus.

needle test points — Sharp steel probes connected to test cords for making contacts with conductors.

neg — Abbreviation for negative.

negate—To invert the value of a function or variable; that is, to change it to 1 if it is 0 or to 0 if it is 1. The symbol for negation is a superscript bar.

negated-input OR gate—A gate that has a high output when one or both inputs are low. A negated-input OR gate is identical with a NAND gate in function.

negation—The NOT operation in Boolean algebra.

negative—Abbreviated neg. 1. Less than zero. 2. The opposite of positive (e.g., negative resistance, transmission, feedback, etc.). 3. A terminal or electrode having an excess of electrons. Electrons flow out of the negative terminal of a voltage source, toward a positive source. 4. An artwork, artwork master, or production master in which the intended conductive pattern is transparent to light, and the areas to be free from conductive material are opaque.

negative acceleration—A relative term often used to indicate that, referenced to zero acceleration, a negative electrical output will be obtained from a linear accelerometer when its sensitive axis is oriented normal to the surface of the earth and a given minus reference point along the center of the seismic mass.

negative acknowledgement character—Abbreviated NAK. A communication control character transmitted from a receiving point as a negative response to a sender. It may also be used as an accuracy control character.

negative bias—In a vacuum tube, the voltage that makes the control grid more negative than the cathode.

negative booster—A booster used with a ground-return system to reduce the difference of potential between two points to the grounded return. It is connected in series with a supplementary insulated feeder extending from the negative bus of the generating station or substation to a distant point on the grounded return.

negative charge—A condition in a circuit when the element in question retains more than its normal quantity of electrons.

negative conductor—A conductor connected to the negative terminal of a source of supply. Such a conductor is frequently used as an auxiliary return circuit in a system of electric traction.

negative differential conductance region—That part of the characteristic of a tunnel diode between the peak and valley points.

negative-effective-mass amplifiers and generators—A class of solid-state devices for broadband amplification and generation of microwave energy. Operation of these devices is based on the phenomenon by which the effective masses of charge carriers in semiconductors become negative when their kinetic energies are sufficiently high.

negative electricity—The type of electricity possessed by a body that has an excess of electrons.

negative electrode—The electrode from which the forward current flows.

negative electron—Also called negatron. An electron, distinguished from a positive electron or positron.

negative feedback—Also called degeneration, inverse feedback, or stabilized feedback. A process by which a part of the output signal of an amplifying circuit is fed back to the input circuit. The signal fed back is 180° out of phase with the input signal; therefore, the amplification is decreased, and distortion reduced.

negative-feedback amplifier—An amplifier in which negative feedback is employed to improve the stability or frequency response, or both.

negative ghost—A ghost that has the opposite shading from that of the original image (i.e., is black when the image is white, and vice versa).

negative glow—The luminous glow between the cathode and Faraday dark spaces in a glow-discharge cold-cathode tube. *See also* glow discharge.

negative-grid generator—A conventional oscillator circuit in which oscillation is produced by feedback from the plate circuit to a grid that is normally negative with respect to the cathode and that is designed to operate without drawing grid current at any time.

negative ground—The negative battery terminal of a vehicle is connected to the body and frame.

negative image—1. A televised picture in which the whites appear black and vice versa. It is due to the picture signal having a polarity opposite to that of a normal signal. 2. A picture signal having a polarity that is opposite to normal polarity and which results in a picture in which the white and black area are reversed.

negative impedance—Also called negative resistance when there is no inductance or capacitance in the circuit. A characteristic of certain electrical devices or circuits—instead of increasing, the voltage decreases when the current is increased, and vice versa.

negative ion—An atom with more electrons than the normal number. Thus, it has a negative charge.

negative-ion generator—A device that bombards air molecules with electrons so that molecules are ionized negatively.

negative light modulation—In television, the process whereby a decrease in initial light intensity causes an increase in the transmitted power.

negative logic—A form of logic in which the more positive voltage level represents logical 0 and the more negative level represents logical 1.

negative modulation—In an AM television system, that modulation in which an increase in brightness corresponds to a decrease in transmitted power.

negative modulation factor—The maximum negative departure of the envelope of an AM wave from its average value, expressed as a ratio. This rating is used whenever the modulation signal wave has unequal positive and negative peaks.

negative phase-sequence relay—A relay that functions in conformance with the negative phase-sequence component of the current, voltage, or power of the circuit.

negative picture phase—1. For a television signal, the condition in which an increase in brilliance makes the picture-signal voltage swing in a negative direction from the zero level. 2. Positioning the composite video signal so that the maximum level of the sync pulses is at 100% amplitude. The brightest picture signals are in the opposite, negative direction.

negative picture transmission—Television transmission system used in North America and other countries in which a decrease in illumination of the original scene causes an increase in percentage of modulation of the picture carrier. When modulated, signals with a higher modulation percentage have more positive voltages.

negative plate—The grid and active material connected to the negative terminal of a storage battery. When the battery is discharging, electrons flow from this terminal, through the external circuit, to the positive terminal.

negative resistance—1. A resistance that exhibits the opposite characteristic from normal—i.e., when the voltage is increased across it, the current will decrease instead of increase. 2. A property of some circuits containing no reactance whereby the current increases as the voltage is decreased.

negative-resistance magnetron—A magnetron operated so that it acts as a negative resistance.

negative-resistance oscillator—An oscillator produced by connecting a parallel-tuned resonant circuit

to a two-terminal negative-resistance device (one in which an increase in voltage results in a decrease in current). Dynatron and transitron oscillators are examples.

negative-resistance region—That operating region in which an increase in applied voltage results in a current decrease.

negative-resistance repeater—A repeater in which gain is provided by a series or shunt negative resistance, or both.

negative temperature coefficient—The amount of reduction in the value of a quantity, such as capacitance or resistance, for each degree of increase in temperature. *See also* temperature coefficient.

negative terminal—In a battery of other voltage source, the terminal having an excess of electrons. Electrons flow from it, through the external circuit, to the positive terminal.

negative torque—A torque developed in opposition to the normal torque of a motor. This may occur at starting—common to pole motors—or at some speed below the nameplate rpm. This causes “cusps” or “saddles” in the graphed torque curves.

negative-transconductance oscillator—An electron-tube oscillator whose output is coupled back to the input without phase shift, the phase condition for oscillation being satisfied by the negative transconductance of the tube. A transitron oscillator is an example.

negative transmission—The modulation of the picture carrier by a picture signal with a polarity such that the sync pulses occur in the blacker-than-black region and a decrease in initial light intensity increases the transmitted power.

negative-true logic—A logic system in which the voltage representing a logical 1 has a lower or more negative value than that representing a logical 0. Most parallel I/O buses use negative-true logic due to the nature of commonly available logic circuits.

negatron—1. An electron. *See also* negative electron. 2. A four-electrode vacuum tube having a negative-resistance characteristic. 3. *See* dynatron.

NEMA—Abbreviation for National Electrical Manufacturers Association.

NEMA standards—Consensus standards for electrical equipment approved by the majority of the members of the National Electrical Manufacturers Association (NEMA).

nematic liquid—An organic chemical used in liquid crystal displays (LCDs) that simultaneously exhibits liquid and crystal properties. It is transparent until the threadlike molecules are disturbed by an electric field; then it takes on a milky-white appearance.

nematic liquid crystal—1. A liquid crystal in such a state that the principal axis of all the molecules is aligned in one direction. This state is the result of the arrangement of the forces between the molecules and the shape of the molecules, keeping the molecules in a low-energy static state, aligned on one axis. 2. Ordered fluid whose molecules lie parallel to each other with their centers of mass randomly distributed. They are organic compounds whose molecules are rodlike in overall shape. The word *nematic* comes from the Greek *nema*, meaning “threadlike.” A threadlike pattern is observed when nematics are viewed through a microscope under polarized light.

nematic phase—1. An arrangement of parallel-oriented liquid crystal molecules. The nematic phase is turbid but much less viscous than the smectic phase, and the molecules are not arranged in layers. 2. A form of the liquid crystals with an appearance of moving, threadlike structures, particularly visible when observed, in thick specimens, with polarized light. During this phase the

molecules of the crystal are parallel and able to travel past each other following the direction of their longitudinal axes. This form has one optical axis that occupies the direction of an applied magnetic field.

nemo—*See* field pickup.

neon—An inert gas used in neon signs and in some electron tubes. It produces a bright red glow when ionized. Symbol, Ne; atomic number 10; atomic weight, 20.183.

neon bulb—A glass envelope filled with neon gas and containing two or more insulated electrodes. The tube will not conduct until the potential difference between two electrodes reaches the firing, or ionization, potential, and will remain conductive until the voltage is reduced to the extinction level.

Neon bulb.

neon-bulb oscillator—A simple relaxation oscillator in which a capacitor charges to the ionization potential of the neon gas within a bulb. Ionization rapidly depletes the charge on the capacitor, and a new charge cycle begins.

FREQUENCY OF SAWTOOTH WAVES CAN BE VARIED BY VARYING RESISTOR R

Circuit.

Output.

Neon-bulb oscillator.

neon indicator tube—A cold-cathode tube containing neon and designed to visually indicate a potential difference or field.

neon oscillator—*See* neon-bulb oscillator.

neon tube—An electron tube containing neon gas that uses the transmission of an electric current through

the gas to ionize the neon and produce a luminous red discharge.

NEP—Abbreviation for noise equivalent power.

neper—Also called nepier. The fundamental division of a logarithmic scale for expressing the ratio between two currents or voltages. The number of nepers denoting such a ratio is the natural (Napierian) logarithm of this ratio. One neper equals 0.8686 bels, or 8.686 decibels. Expressed as a formula:

$$N = \log_e(E_1/E_2)$$

where N is the number of nepers and E_1 and E_2 are the two voltages.

Nernst effect—The effect whereby a potential difference is developed across a heated metal strip placed perpendicular to a magnetic field.

Nernst-Ettinghausen effect—A thermomagnetic effect that occurs in certain pure crystals, whereby a temperature difference is produced in a direction perpendicular to an applied magnetic field and a longitudinal electric current.

Nernst lamp—An electric lamp consisting of a short, slender rod of zirconium oxide that is heated to incandescence by a current.

nest—To enclose a subroutine inside a larger routine, but not necessarily make it part of the outer routine. A series of looping instructions can be nested within each other.

nested subroutine—In a computer program, the subroutine called within another subroutine.

nesting—1. A term used to indicate that a subroutine in a computer is enclosed inside a larger routine, but is not necessarily part of the outer routine. A series of looping instructions may be nested within each other. 2. A programming technique in which a segment of a larger program is executed iteratively (looping) until a specific data condition is detected or until a predetermined number of interactions has been performed. The nesting technique allows a program segment to be nested within a larger segment and that segment to be nested within an even larger segment. 3. A programming technique involving the embedding of routines within other routines.

nesting level—The number of times nesting can be repeated.

net—1. Organization of stations capable of direct communications on a common channel, often on a definite schedule. 2. Also known as a signal. Collection of part and connector pins that must be connected. 3. One complete circuit connecting at least one output to at least one input. Must be some form of conductor, such as a wire. 4. The common abbreviation for the Internet.

net authentication—Identification used on a communications network to establish the authenticity of several stations.

net control station—Communications station having the responsibility of clearing traffic and exercising circuit discipline within a net.

net information content—A measure of the essential information contained in a message. It is expressed as the minimum number of bits or hartleys required to transmit the message with specified accuracy over a noiseless medium.

netlist—List of names, symbols, and their connection points that are logically connected in a net.

net loss—The algebraic sum of the gains and losses between two terminals of a circuit. It is equal to the difference in the levels at these points.

net reactance—The difference between the capacitive and inductive reactance in an ac circuit.

Netscape—A graphical web browser.

Netscape Communications—A company whose primary products are a graphical web browser called Netscape Navigator (sometimes known simply as Netscape) and HTTP server software named Netsite.

Netscape Navigator—The graphical web browser developed by Netscape Communications.

Netsite—The HTTP server software developed by Netscape Communications.

network—1. A combination of electrical elements. 2. An interconnected system of transmission lines that provides multiple connections between loads and sources of generation. 3. An organization of stations with a capability for intercommunication, although not necessarily on the same channel. 4. Two or more interrelated circuits. 5. Decentralized computer architecture that retains the access-to-information characteristic of a centralized computer. The key feature of a network is that communication between the computers in the network is really communication between the programs running on those computers. 6. A complex of two or more interconnected computers. The hardware that supports it generally includes multiplexers, line adapters, modems, and computers with associated peripherals. Software products used consist of modules in the host computer's operating systems, front-end processors, and remote processors that handle services provided to users. 7. A structured connection of computer systems and/or peripheral devices, each remote from the others, exchanging data as necessary to perform the specific function of the connection. 8. The interconnection of a number of points by data communications facilities.

network analog—The expression and solution of a mathematical relationship between variables through the use of a circuit or circuits to represent those variables.

network analysis—1. The obtaining of the electrical properties of a network (e.g., its input and transfer impedances, responses, etc.) from its configuration, parameters, and driving forces. 2. The process of creating a data model of transfer and/or impedance characteristics of a linear network through sine-wave testing over the frequency range of interest.

network analyzer—1. A group of electric-current elements that can readily be connected to form models of electric networks. From corresponding measurements on the model, it is then possible to infer the electrical quantities at various points on the prototype system. 2. Also called network calculator. An analog device designed primarily for simulating electrical networks. 3. An instrument that evaluates the impedance characteristics of linear networks over a range of frequencies.

network architecture—1. A descriptive phrase for the combination of hardware and software that comprises a computer network. 2. A set of rules, standards, or recommendations through which various computer hardware, operating systems, and applications software function together.

network calculator—An analog device designed primarily for simulating electric networks.

network constant—Any one of the resistance, inductance, mutual-inductance, or capacitance values in a circuit or network. When these values are constant, the network is said to be linear.

network filter—1. A transducer for separating waves on the basis of their frequency. 2. A combination of electrical elements, e.g., interconnected resistors, coils, and capacitors, that presents relatively small attenuation to signals of certain frequency and great attenuation to all other frequencies.

network master relay—A relay that closes and trips an alternating-current, low-voltage network protector.

network phasing relay—A relay that functions in conjunction with a master relay to limit closure of the network protector to a predetermined relationship between the voltage and the network voltage.

network relay—A form of relay (e.g., voltage, power) used in the protection and control of alternating-current, low-voltage networks.

network synthesis—1. The obtaining of a network from prescribed electrical properties such as input and transfer impedances, specified responses for a given driving force, etc. 2. The process of deriving the configuration and component values of a network with given performance specifications.

network topology—The physical and logical relationship of nodes in a computer network; the schematic arrangement of the links and nodes of a network; networks typically have a star, ring, tree, or bus topology, or some hybrid combination.

network transfer function—A frequency-dependent function, the value of which is the ratio of the output to the input voltage.

network transformer—A transformer suitable for use in a vault to feed a variable-capacity system of interconnected secondaries.

Neuman's law—Mutual inductance is a constant for a given relative physical position of coils, and is independent of the fact that the current flows in one or the other coil, and of frequency, current, and phase.

neural network—A set of linked microprocessors that can form associations and learn like the neurons in a human brain.

neuristor—1. A two-terminal active device with some of the properties of neurons (e.g., propagation that suffers no attenuation and has a uniform velocity and a refractory period). 2. A device that is essentially an active transmission line designed to propagate signals without attenuation. It is an electrical analog of a nerve fiber.

neuroelectricity—The minute electric voltage generated by the nervous system.

neuron—The basic building block of the human nervous system. A specialized body cell that can conduct and code an electrical pulse.

neutral—In a normal condition; hence, neither positive nor negative. A neutral object has its normal number of electrons—i.e., the same number of electrons as protons.

neutral circuit—A teletypewriter circuit in which current flows in only one direction. The circuit is closed during the marking condition and open during the spacing condition.

neutral conductor—That conductor of a polyphase circuit or of a single-phase three-wire circuit that is intended to have a potential such that the potential differences between it and each of the other conductors are approximately equal in magnitude and are also equally spaced in phase.

neutral density filter—A light filter that reduces the intensity of light without changing the spectral distribution.

neutral ground—A ground connection to the neutral point or points of a circuit, transformer, rotating machine, or system.

neutralization—1. The nullifying of voltage feedback from the output to the input of an amplifier through the interelectrode impedance of the tube. Its principal use is in preventing oscillation in an amplifier. This is done by introducing into the input a voltage equal in magnitude but opposite in phase to the feedback through the interelectrode capacitance. 2. The process that prevents unwanted self-oscillation in an amplifier by feeding back part of the amplified signal, out of phase, to the input.

neutralize—In an amplifier stage, to balance out the feedback voltage due to grid-plate capacitance, thus preventing regeneration.

neutralized radio-frequency stage—A stage in which a circuit is added for the purpose of feeding back, in the opposite phase, an amount of energy sufficient to cancel the energy that would otherwise cause oscillation.

neutralizing capacitor—A capacitor, usually variable, employed in a radio receiving or transmitting circuit to feed a portion of the signal voltage from the plate circuit back to the grid circuit.

Neutralizing capacitor.

neutralizing circuit—In an amplifier circuit, the portion that provides an intentional feedback path from plate to grid. This is done to prevent regeneration.

neutralizing indicator—An auxiliary device (e.g., a lamp or detector) coupled to the plate tank circuit of an amplifier for indicating the degree of neutralization in an amplifier.

neutralizing tool—Also called a tuning wand. 1. A small screwdriver or socket wrench, partly or entirely nonmetallic, for making neutralizing or aligning adjustments in electronic equipment. *See also* alignment tool. 2. A plastic rod having a ferrite plug in one end and a brass plug in the other end. Used to check the tuning of radio-frequency circuits. When inserted in a coil, the ferrite increases the inductance while the brass decreases the inductance.

neutralizing voltage—The ac voltage fed from the grid circuit to the plate circuit (or vice versa). It is deliberately made 180° out of phase with and equal in amplitude to the ac voltage similarly transferred through undesired paths (usually the grid-to-plate interelectrode capacitance).

neutral operation—The system whereby marking signals are formed by current impulses of one polarity, either positive or negative, and spacing signals are formed by reducing the current to zero or nearly zero.

neutral point—The point that has the same potential as the point of junction of a group of equal nonreactive resistances connected at their free ends to the appropriate main terminals or lines of the system.

neutral relay—Also called a nonpolarized relay. 1. A relay in which the armature movement does not depend on the direction of the current in the controlling circuit. 2. A relay whose operation depends on the magnitude of the current through its operating winding, and not on the current's direction.

neutral section—That section through a magnet where the center line would pass.

neutral signals—Signals sent in the form of direct-current pulses for marks and an absence of current for spaces.

neutral transmission—Also called unipolar transmission. Transmission of teletypewriter signals in such a way that a mark is represented by current on the line, and a space is represented by the absence of current. By extension to tone signaling, a method of signaling involving two states, one of which represents both a space and the absence of signaling.

neutral zone—A range in the total control zone in which a controller does not respond to changes in the controlled process; a dead zone, usually in the middle of the control range.

neutrodyne—An amplifier circuit used in early tuned radio-frequency receivers. It is neutralized by the voltage fed back by a capacitor.

neutron—One of the three elementary particles (the electron and proton are the other two) of an atom. It has approximately the same mass as the hydrogen atom, but no electric charge. It is one of the constituents of the nucleus (the proton is the other one).

newsgroups—Discussion groups on Usenet. *See also* Usenet

newton—In the mksa system, the unit of force that will impart an acceleration of 1 meter per second to a mass of 1 kilogram. Letter symbol: N.

nF—Letter symbol for nanofarad.

n-gate thyristor—A thyristor in which the gate terminal is connected to the n region nearest the anode and which is normally switched to the on state by applying a negative signal between the gate and anode terminals.

nibble—Also nybble. 1. A sequence of 4 bits operated upon as a unit. *See* byte. 2. One half of a byte. 3. The first or last half of an 8-bit byte (4 bits). 4. Half of a byte (4 bits). Binary coded decimal (BCD) is packed into nybbles.

nibble mode—A form of DRAM addressing in which 4 sequential bits (a nibble) are accessed.

Nichrome—Trade name of Driver-Harris Co. for an alloy of nickel and chromium used extensively in wirewound resistors and heating elements.

nick—A small cut or notch in conductor strands or insulation.

nickel—A metal that offers combination of corrosion resistance, formability, and tough physical properties. For these reasons, nickel is used for alloying purposes and in nickel-clad copper wire.

nickel-cadmium cell—The most widely used rechargeable sealed cell, nickel-cadmium gives a flat voltage discharge characteristic, nominal cell voltage of 1.25 volts, and good low-temperature operation. A cell with a nickel and oxide positive electrode and a cadmium negative electrode. The plates are wrapped with a separator between them, and are immersed in a potassium-hydroxide electrolyte.

nickel-clad copper wire—A wire with a layer of nickel on a copper core, where the area of the nickel is approximately 30 percent of the conductor area. The nickel has been rolled and fused to the copper before drawing.

nickel-metal hydride—Abbreviated NiMH. A rechargeable battery technology that largely overcomes the "memory loss" problems of nickel-cadmium batteries. It can also store a greater charge than a comparable size Nicad battery.

nickel-oxide film diode—A solid-state diode made of nickel-oxide film. It may be switched from off to on by applying a 300-volt low-current pulse for 10 μ s, and may be switched from on to off by applying a 30-volt

Nickel-cadmium cell.

high-current pulse for 10 μ s. In effect it works like a dipole flip-flop.

nickel silver—*See* German silver.

NIF—Abbreviation for noise-improvement factor.

night-vision devices—Devices that use low-level visible radiation or infrared radiation to produce a visual image of a night scene as it would appear in daylight. These devices may rely on the amplification of existing visible light by photomultiplier tubes or infrared recording.

ni junction—A semiconductor junction between n-type and intrinsic materials.

NiMH—Abbreviation for nickel-metal hydride.

nines complement—1. A decimal digit that yields 9 when added to another decimal digit. 2. Pertaining to an arithmetic method of negating a decimal number so that subtraction can be performed by using addition techniques. The nines-complement negation of a number results from subtracting each decimal digit individually from 9. End-around carry must be used in performing a nines-complement addition.

Nipkow disc—A round plate used for scanning small elementary areas of an image in correct sequence for a mechanical television system. It has one or more spirals of holes around its outer edge, and successive openings are positioned so that rotation of the disc provides the scanning.

Nipkow disc TV system.

NIPO—Acronym for negative input, positive output.

N-ISDN—Abbreviation for narrowband integrated services digital network. Opposite of B-ISDN (broadband

ISDN). N-ISDN operates at channel speeds less than B-ISDN and has less bandwidth for asynchronous transfer mode-like transmission.

nit—1. In a computer, a choice among events that are equally probable. One nit equals 1.44 bits. 2. The unit of luminance (photometric brightness) equal to 1 candela per square meter. Letter symbol: nt.

Nixie tube—A glow tube that converts a combination of electrical impulses into a visual display. *See also* numerical-readout tube.

Nixie-tube display—A form of display composed of a number of neon-filled tubes, each containing wires in the shape of the digits 0 to 9, with separate wires for each digit. On signal, the correct wires are energized, causing the neon gas around the wires to glow.

n-level logic—Pertaining to a collection of gates connected in such a way that not more than *n* gates appear in series.

NMOS—Abbreviation for n-channel metal-oxide semiconductor. 1. Pertaining to MOS devices made on p-type silicon substrates in which the active carriers are electrons that flow between n-type source and drain contacts. The opposite of PMOS, where n-type source and drain regions are diffused into p-type substrate to create an n-channel for conduction. NMOS is from two to three times faster than PMOS. 2. N-channel circuits, using currents made up of negative charges and producing devices at least twice as fast as PMOS and having the potential for high-density configurations. 3. A form of metal-oxide silicon transistor in which the charge flow from source to drain is electrons.

NMOS silicon-gate technology—A process used by National Semiconductor to design and fabricate high-density, high-performance microcomputer components. The process features scaled-geometry transistors (2- μ m active length), of a variety of threshold voltages, to optimize the speed/power performance of the internal circuitry.

n-n junction—In an n-type semiconducting material, a region of transition between two regions having different properties.

no—Abbreviation for normally open.

no-address instruction—An instruction specifying an operation that the computer can perform without having to refer to its storage or memory unit.

noble—Chemically inert. A term often used to describe metals such as gold, platinum, etc.

noble gas—Also called inert gas or rare gas. One of the chemically inert gases, including helium, neon, argon, krypton, and xenon.

noble-metal paste—A soft, moist, smooth compound made up partially of precious metals such as gold, platinum, ruthenium, or others classed as noble metals, providing conductors in film circuitry.

noble system—Thick-film system using conductors of gold, platinum, and possibly palladium silver, or certain alloys of these precious metals.

no contacts—Contacts that are normally open when the control circuit is not energized.

noctovision—1. A television system employing invisible rays (usually infrared) for scanning purposes at the transmitter. Hence, no visible light is necessary. 2. A television system used for seeing in the dark, particularly with the use of infrared rays.

nodal-point keying—Keying an arc transmitter at a point that is essentially at ground potential in the antenna circuit.

nodal points—1. Two points on the axis of a lens such that a ray entering the lens in the direction of one leaves as if from the other and parallel to the original direction. 2. *See* node, 2.

node—Also called junction point, nodal point, branch point, or vertex. 1. A terminal of any branch of a network, or a terminal common to two or more branches. 2. The point, line, or surface in a standing-wave system where some characteristic of the wave field has essentially zero amplitude. The appropriate modifier should be used with the word *node* to signify the type that is intended (e.g., pressure node). 3. Provides data entry/exit point in computers and terminals, and switches or processes data. Smart terminals and smart programmable controllers—the ones based on microprocessors—also have true processing capability and qualify as nodes. Each node is potentially capable of performing application-oriented tasks. 4. A junction between interconnected integrated circuits on a logic board. 5. Any point in a communications network that is individually addressable, be it a terminal, computer, or communications controller. 6. A point of interconnection to a network common to two or more branches of a network. Normally, a point at which a number of terminals are located.

nodules—Clusters of oxide particles that protrude above the surface of magnetic tape.

noise—1. Any unwanted disturbance within a dynamic electrical or mechanical system (e.g., undesired electromagnetic radiation in a transmission channel or device). 2. Any unwanted electrical disturbance or spurious signal that modifies the transmitting, indicating, or recording of desired data. 3. In a computer, extra bits or words that have no meaning and must be ignored or removed from the data at the time it is used. 4. Random electrical variations generated internally in electronic components. 5. In acoustics, a potentially distracting or distorting sensory pattern. 6. Any sounds that are not harmonically related to the signal and are added subsequently by recording or playback equipment (includes hiss, crackles, hum, rumblings, ticks, pops, etc.). Each recording system has its own set of inherent noise-producing components. 7. Any unwanted addition of frequencies unrelated to the signal that tends to obscure the signal information. In audio, noise is usually heard as hiss (random noise) or as hum (the power-line frequency and its harmonics). Since signals must be, in general, stronger than the noise level in order to convey information, noise defines the lower limits of a component's dynamic range. (The upper limit is imposed by the maximum tolerable distortion.) Noise may be defined in terms of absolute levels, but in audio equipment it is usually defined in decibels below the maximum tolerably distorted signal. 8. Random, unwanted electrical signals that can cause unwanted and false output signals in a circuit. For example, a random noise pulse might trigger a digital circuit, thereby producing a binary 1 at the circuit output where a binary 0 should be present. 9. An unwanted voltage fluctuation generated within a resistor. Total noise of a resistor always includes Johnson noise, which is dependent only on resistance value and temperature of the resistance element. Depending on type of element and construction, total noise may also include noise caused by current and noise caused by cracked bodies and loose end caps or leads. For variable resistors, noise may also be caused by jumping of contact over turns of wire and by an imperfect electrical path between contact and resistance elements. 10. The unwanted and unpredictable fluctuations that distort a received signal and, hence, tend to obscure the desired message. Noise disturbances, which may be generated in the devices of a communications system or which may enter the system from the outside, limit the range of the system and place requirements on the signal power necessary to ensure good reception. 11. A communication-line impairment inherent in the line design or induced by

transient energy bursts. 12. Unwanted components, other than distortion, added to a signal or sound. 13. Random bursts of electrical energy or interference. In some cases, it will produce a salt-and-pepper pattern over a televised picture. Heavy noise is sometimes referred to as snow. 14. Random signals or other interference on a line. 15. The unpredictable or random difference between the observed data and the true process.

noise analysis—Determination of the frequency components that make up the noise being studied.

noise analyzer—An instrument used for determining the amplitude versus frequency characteristics of noise.

noise bandwidth—The width of the equivalent rectangular power gain versus frequency response of a network. It is the width of the rectangle whose area equals that of the actual power gain versus frequency response and whose height equals the maximum available power gain at a reference frequency f_0 . It does not include any spurious responses. Any responses other than those in the useful channel are accounted for by a degraded noise figure.

noise behind the signal—See modulation noise.

noise blanker—1. A circuit used in some receivers just before the detector to minimize ignition noise. 2. Circuit for reducing noise interference. It is usually placed in the rf section or at the beginning of the IF section of a receiver, before the high-selectivity circuits. It squelches the receiver for a very short period (the width of the noise spike). Noise blankers are more effective than noise limiters, but their circuitry is more complex.

noise-canceling microphone—A microphone that is built in such a way as to minimize transmission of any background noise at the transmitting site. See also close-talking microphone.

noise clipper—A circuit that automatically or manually clips the noise from the output of a receiver.

noise-criteria value—Also called NC value. A measure of background noise; it is a single overall value determined from the greatest level of sound pressure of several individual frequency bands. Sometimes values are stated for each band.

noise current—The equivalent open-circuit rms noise current that occurs at the input of a noiseless amplifier due to current at that input. It is measured by shunting an impedance across the input terminals and comparing this output noise with the output noise obtained when the input is shorted.

noise-current generator—A current generator in which the output is a random function of time.

noise diode—A standard electrical-noise source consisting of a diode operated at saturation. The noise is due to random emission of electrons.

noise equivalent bandwidth—The useful bandwidth of a thermistor bolometer for various frequencies in the input radiation, equal to $1/4t$ (where t is the time constant of the bolometer).

noise equivalent power—Abbreviated NEP. 1. The value of radiation that produces, in a detector, an rms signal-to-noise ratio of unity. It is usually measured with a blackbody radiation source at 500 K and a bandwidth of 1 or 5 hertz. The modulation rate varies with the type of detector and is usually between 10 and 1000 hertz. 2. The minimum detectable signal equal to the ratio of total detector and system noise to responsivity.

noise factor—Also called noise figure. 1. For a given bandwidth, the ratio of total noise at the output to the noise at the input. 2. A number expressing the amount by which a receiver falls short of equaling the theoretical optimum performance. 3. The ratio of the available signal-to-noise power ratio at the input to the

available signal-to-noise power ratio at the output of a semiconductor device.

noise figure—Abbreviated NF. 1. The ratio of the total noise power at the output of an amplifier to that portion of the total output noise power attributable to the thermal agitation in the resistance of the signal source. See also noise factor. 2. In a network with a generator connected to its input terminal, the ratio of the available signal-to-noise-power ratio at the signal-generator terminals (weighted by the network bandwidth) to the available signal-to-noise-power ratio at the output. 3. The common logarithm of the ratio of the input signal-to-noise ratio to the output signal-to-noise ratio.

noise filter—1. A combination of electrical components that prevents extraneous signals from passing into or through or out of an electronic circuit. 2. Combination of one or more coils and capacitors inserted between the power cord of a receiver and a wall outlet to block noise interference that might otherwise reach the receiver through the power line.

noise floor—The lowest input signal power level that will produce a detectable output signal from a microwave component, determined by the thermal noise generated within the microwave component itself. The noise floor limits the ultimate sensitivity to the weak signals of the microwave system, since any signal below the noise floor will result in an output signal with a signal-to-noise ratio of less than 1 and will be more difficult to recover.

noise-free environment—A space theoretically containing neither electrostatic nor electromagnetic radiation.

noise generator—An electronic device that generates wide-band white noise for use in testing. The generator output is obtained by amplifying low-level white noise obtained from a source such as a photomultiplier.

noise grade—A number that defines the noise at a particular location relative to the noise at other locations throughout the world.

noise immunity—1. A measure of the insensitivity of a logic circuit to spurious or undesired electrical signals or noise. 2. See dc noise margin. 3. A measure of a receiver's ability to prevent valid signals from being rejected as noise. It is sometimes specified as the ability of a receiver to operate under conditions of Gaussian noise. 4. A device's ability to discern valid data in the presence of noise.

noise-improvement factor—Abbreviated NIF. In a receiver, the ratio of output signal-to-noise ratio to the input signal-to-noise ratio. (The term receiver is used in the broad sense and is taken to include pulse demodulators.)

noise index—The ratio of the rms current-noise voltage (over a 1-decade bandwidth) to the average (dc) voltage caused by a specified constant current passed through a resistor at a specified hot-spot temperature (usually expressed either in microvolts per volt or in decibels of voltage ratio).

noise jamming—See jamming.

noise killer—An electric network inserted into a telegraph circuit (usually at the sending end) to reduce interference with other communication circuits.

noise level—1. The strength of extraneous audible sounds at a given location. 2. The strength of extraneous signals in a circuit. Noise level is referred to a specified base and usually measured in decibels. 3. A volume of noise energy, specified as so many decibels above a reference level.

noise limiter—Also called a series-gate noise limiter. 1. A circuit that cuts off all noise peaks stronger than the highest peak in the received signal. In this way, the

effects of strong atmospheric or man-made interference are reduced. 2. A circuit that shaves off the noise spikes riding on the desired signal. Usually, diodes are used to obtain the clipping action. When the circuit operates at a predetermined threshold without any user activation, it is called an automatic noise limiter, or ANL. These diode noise limiters are usually in the intermediate-frequency or audio-frequency sections of the receiver.

noise margin—1. The extraneous-signal voltage amplitude that can be added algebraically to the noise-free worst-case input level of a logic circuit before deviation of the output voltage from the allowable logic levels occurs. In this application, the term input generally refers to logic input terminals, ground reference terminals, or power supply terminals. 2. The difference between the operating voltage and the threshold voltage of a binary logic circuit.

noise-measuring set—*See* circuit-noise meter.

noise-modulated jamming—Random electronic noise that appears at a radar receiver as background noise and tends to mask the desired radar echo or radio signal.

noise pulse—Also called noise spike. A spurious signal of short duration and of a magnitude considerably in excess of the average peak value of the ordinary system noise.

noise quieting—The ability, usually expressed in decibels, of a receiver to reduce background noise in the presence of a desired signal.

noise ratio—The ratio of the available noise power at the output of a circuit to the noise power at the input.

noise-reducing antenna system—A receiving-antenna system so designed that only the antenna proper can pick up signals. It is placed high enough to be out of the noise-interference zone, and is connected to the receiver with a shielded cable or twisted transmission line that is incapable of picking up signals.

noise source—A device employed to generate random noise (e.g., photomultiplier and gaseous-discharge tubes).

noise spike—*See* noise pulse.

noise suppression—1. The ability of a radio receiver to materially reduce the noise output when no carrier is being received. 2. A means of reducing surface noise during reproduction of a phonograph record.

noise suppressor—1. A circuit that reduces high-frequency hiss or noise. It is utilized primarily with phonograph records. 2. In a receiver circuit, the portion that reduces noise automatically when no carrier is being received. 3. Any device intended to reduce the audibility of background noise.

noise temperature—1. At a pair of terminals and a specific frequency, the temperature of a passive system having an available noise power per unit bandwidth equal to that of the actual terminals. 2. The temperature at which the thermal noise available from a device equals the total fluctuation noise actually available from the device. 3. A measure of the amount of thermal noise present in a system or a device. The lower the noise temperature, the better the performance.

noise voltage—The equivalent short-circuit input rms noise voltage that occurs at the input of a noiseless amplifier if the input terminals are shorted. It is measured at the output and divided by the amplifier gain and the square root of the bandwidth over which the measurement is made to yield units of nanovolts per square root of hertz.

noise-voltage generator—A voltage generator whose output is a random function of time.

noisy mode—In a computer, a floating-point arithmetic procedure associated with normalization. In this procedure, digits other than 0 are introduced in the low-order positions during the left shift.

no-load current—*See* exciting current, 1.

no-load losses—The losses in a transformer when it is excited at the rated voltage and frequency, but is not supplying a load.

nominal—The identifying value of a measurable property in a conductor or component. This standard value is halfway between maximum and minimum limits of the tolerance range.

nominal band—In a facsimile-signal wave, the frequency band equal to the width between the zero and the maximum modulating frequency.

nominal bandwidth—1. The difference between the nominal upper and lower cutoff frequencies of a filter. It may be expressed in octaves, in hertz, or as a percentage of the passband center frequency. 2. The maximum band of frequencies, inclusive of guard bands, assigned to a channel.

nominal horsepower—The rated power of a motor, engine, etc.

nominal impedance—The impedance of a circuit under normal conditions. Usually it is specified at the center of the operating-frequency range.

nominal line pitch—The average separation between the centers of adjacent lines in a raster.

nominal line width—1. In television, the reciprocal of the number of lines per unit length in the direction of line progression. 2. In facsimile transmission, the average separation between centers of adjacent scanning or recording lines.

nominal power rating of a resistor—The power that a resistor can dissipate continuously at a specified ambient temperature and for a stipulated length of time without excessive resistance drift.

nominal value—The stated or specified value, as opposed to the actual value.

nominal voltage—1. The voltage of a fully charged storage cell when delivering rated current. 2. Average source voltage.

nomogram—Also called an alignment chart or nomograph. A computational aid consisting of two or more scales drawn and arranged so that the results of calculations may be found by the linear connection of points on them.

nomograph—*See* nomogram.

nomography—A method of representing the relation between any number of variables graphically on a plane surface such as a piece of paper.

nonblinking—The ability of a digital meter display to appear steady and free of blinking. Usually achieved by storing the reading during the same period.

nonbridging—A contact transfer in which the movable contact leaves one contact before touching the next.

nonbridging contacts—A contact arrangement in which the opening of one set of contacts occurs before the closing of another set.

noncoherent bundle—An assembly of optical fibers that will not transmit coherent images or information because the relationship of the fibers on either end of the assembly is different; can be applied to information scrambling.

noncoherent radiation—Radiation in which the waves are out of phase with respect to space and/or time.

noncombustible—*See* nonflammable.

noncomposite video—A video signal containing all information except sync.

nonconductor—1. An insulating material—i.e., one through which no electric current can flow. 2. A substance that does not transmit certain forms of energy, such as sound, heat, and especially electricity.

noncontiguous allocation—An allocation method that assigns physically nonadjacent sectors to a file.

noncorrosive flux—A flux that does not contain acid and other substances that might corrode the surfaces being soldered.

nondegenerate amplifier—A parametric amplifier in which the pumping frequency is considerably higher than twice the signal frequency. The output is at the input-signal frequency. This type of amplifier has negative impedance characteristics, and therefore is capable of oscillation.

nondestructive readout—A type of memory operation or device in which reading out does not cause stored data to be lost from the memory. Such memories, therefore, do not require a write operation immediately after each read operation, as do destructive types.

nondeviated absorption—1. Absorption that occurs without any appreciable slowing up of waves. 2. Normal sky-wave absorption.

nondirectional—See omnidirectional.

nondirectional antenna—See omnidirectional antenna.

nondirectional microphone—See omnidirectional microphone.

nondissipative stub—A lossless length of waveguide or transmission line coupled into the sides of a waveguide.

nonequivalence element—A logic element having an action that represents the exclusive-OR Boolean connective.

nonerasable storage—In a computer, a storage medium that cannot be erased and reused, e.g., punched cards, perforated paper tape, or a ROM.

nonessential loads—Electrical loads that are not necessary for plant operation, but may be desirable to maintain during longer than commercial power outages. Such loads include some lighting loads, some air-conditioning loads, and equipment used on a part-time basis.

nonfatal error—An error in a computer program that does not substantially affect the progress of the program.

nonferrous—Not made of or containing iron.

nonflammable—Also called noncombustible. Term applied to material that will not burn when exposed to flame or elevated temperatures, e.g., asbestos, ceramics, and structural metals.

nonhoming tuning system—A motor-driven automatic tuning system in which the motor starts in the direction of the previous rotation. If this direction is incorrect for the new station, the motor reverses, after turning to the end of the dial, and then proceeds to the desired station.

nonimpact printer—1. A class of printers that forms images on paper without using a form of stamping or inking through a ribbon by an element, character slug, or hammer-needle. The shapes of the characters are stored in the system memory of the printer and are used to drive the imaging mechanism. 2. A high-speed printer using either thermal, optical, chemical, or electrical techniques. The speed of such a printer is from 30 to 21,000 lines per minute. Generally requires special paper to convert to readable copy. 3. A device that does not rely on mechanical force to print data. Methods such as heat or electricity are used instead.

nonimpact printing—Printing processes in which characters are transferred to paper by means other than physically striking the paper with a key-driven hammer; in nonimpact printing, characters are created by ink jets, thermal devices, or lasers.

noninductive—Having practically no inductance.

noncontiguous allocation — nonlinear distortion

noninductive capacitor—Also called extended foil capacitor. A capacitor in which the inductive effects at high frequencies are reduced to a minimum. Foil layers are offset during winding so that an entire layer of foil (projecting at either end) is connected together for contact-making purposes. A current then flows laterally rather than spirally around the capacitor, and the inductive effect is minimized.

noninductive circuit—A circuit in which the inductance is reduced to a minimum or negligible value.

noninductive load—A load that has no inductance. It may consist entirely of resistance or capacitance.

noninductive resistor—1. A wirewound resistor with little or no self-inductance. 2. A resistor constructed in such a manner that its inductance is negligible.

noninductive winding—A winding in which the magnetic fields produced by its two parts cancel each other and thereby provide a noninductive resistance.

non-interlaced—A method of sending a video image to a monitor that scans each successive video line of a picture so a full picture is painted onto the screen in one vertical sweep of the electron beam. At any given resolution, non-interlaced modes are preferable to interlaced modes but are more expensive to generate. Standard VGA (640 × 480) and SVGA (800 × 600) are always non-interlaced. See interlaced scanning.

noninverting connection—The closed-loop connection of an operational amplifier when the forward gain is positive for a dc signal (0° phase shift).

noninverting input—A differential-amplifier input terminal for which the output signal has the same phase as the input signal.

noninverting parametric device—A parametric device whose operation depends essentially upon three frequencies—a harmonic of the pump frequency and two signal frequencies—of which one is the sum of the other plus the pump harmonics. Such a device can never provide gain at either of the signal frequencies. It is said to be noninverting because if either of the two signals is moved upward in frequency, the other will move upward in frequency.

nonionizing radiation—1. Radiation that does not produce ionization (e.g., infrared, ultraviolet, and visible light). 2. Radiation that does not produce free electrons and ions, or electrically charged particles.

nonlinear—1. Having an output that does not rise or fall in direct proportion to the input. 2. Characteristic of any device in which the output is not related to the input by a simple constant. Not proportional.

nonlinear capacitor—A capacitor that has a nonlinear mean-charge characteristic or peak-charge characteristic or a reversible capacitance that varies with bias voltage.

nonlinear coil—A coil with an easily saturable core. Its impedance is high at low or zero current, and is low when enough current flows to saturate the core.

nonlinear distortion—1. Distortion that occurs when the output does not rise and fall directly in proportion to the input. The input and output values need not be of the same quantity—e.g., in a linear detector, these values are the signal voltage at the output and the modulation envelope at the input. 2. Distortion that occurs because the transmission properties of a system are dependent on the instantaneous magnitude of the transmitted signal. Note: Nonlinearity distortion gives rise to amplitude and harmonic distortion intermodulation and to flutter. 3. The generation of unwanted signals as a result of nonlinear operations on a desired signal or group of signals. (Harmonic distortion is one well-known example; if the main signal is a sine wave of frequency f , the unwanted signals appear as sine waves at $2f$, $3f$, and so on.) 4. Distortion

in an electrical system in which the ratio of voltage to current in the system varies as a function of either the voltage or current.

nonlinear feedback control system—Feedback control system in which the relationships between the pertinent measures of the system input and output signals cannot be adequately described by linear means.

nonlinearity—The amount by which the measured output of a transducer, subjected to any load within its capacity, differs from an ideally linear output as defined by a straight line. The transducer output is measured on increasing load only.

nonlinear network—A network (circuit) not specifiable by linear differential equations with time as the independent variable.

nonlinear optical effects—Optical phenomena that can be observed only with the use of directional, nearly monochromatic light beams, such as those produced by a laser. Examples are optical mixing, harmonic generation, and the stimulated raman effect.

nonlinear programming—Similar to linear programming but incorporating a nonlinear objective function and linear constraints, or a linear objective function and nonlinear constraints, or both a nonlinear objective and nonlinear constraints.

nonloaded Q— Also called basic Q . The value of the Q of an electric impedance without external coupling or connection.

nonmagnetic—Material that is not attracted by a magnet and cannot be magnetized (e.g., paper, plastic, tin, glass). In a strict sense, having a permeability equal to that of air or 1.

nonmagnetic steel—A steel alloy that contains about 12 percent manganese, and sometimes a small quantity of nickel. It is practically nonmagnetic at ordinary temperatures.

nonmetallic sheathed cable—Two or more rubber- or plastic-covered conductors assembled in an outer sheath of nonconducting fibrous material that has been treated to make it flame and moisture resistant.

nonmultiple switchboard—A manual telephone switchboard in which each subscriber line is connected to only one jack.

nonnoble system—Thick-film system using conductors of copper, tungsten, nickel, molybdenum, and other nonnoble metals.

nonphysical primary—A color primary represented by a point outside the area of the chromaticity diagram enclosed by the spectrum locus and the purple boundary.

nonplanar network—A network that cannot be drawn on a plane without crossing branches.

nonpolar capacitor—*See* bipolar electrolytic capacitors.

nonpolar crystals—Crystals having the property that each lattice point is identical.

nonpolar electrolytic capacitor—An electrolytic capacitor that can be connected without regard to polarity. This is possible because the dielectric film is formed on both electrodes.

Nonpolar electrolytic capacitor.

nonpolarized relay—*See* neutral relay.

nonrecursive filter—*See* digital filter.

nonrenewable fuse unit—A fuse unit that cannot be readily restored for service after operation.

nonreset timer—A timer that cannot be reset by electrical means.

nonresonant line—A transmission line with a neutral resonant frequency different from that of the transmitted signal.

nonreturn-to-zero—A method of writing information on a magnetic surface in which the current through the write-head winding does not return to zero after the write pulse.

nonsaturated color—A color that is not pure—i.e., one that has been mixed with white or its complementary color.

nonsaturated logic—A type of logic circuit in which short delay times are achieved by preventing transistors from saturating.

nonshorting switch—Switch in which the width of the movable contact is less than the distance between contact clips so that one circuit is broken before another is completed.

non simultaneous transmission—Usually, transmission in which data can be moved in only one direction at a time by a device or facility.

nonsinusoidal wave—Any wave that is not a sine wave. It therefore contains harmonics.

nonstorage camera tube—A television camera tube in which the picture signal is always in proportion to the intensity of the illumination on the corresponding area of the scene being televised.

nonswitched line—A communications link that is permanently installed between two points.

nonsynchronous—Not related in frequency, speed, or phase to other quantities in a device or circuit.

nonsynchronous starting torque—The maximum load torque with which motors can start. However, the motor will not come to a synchronous speed.

nonsynchronous vibrator—A vibrator that interrupts a direct-current circuit at a frequency unrelated to the other circuit constants. It does not rectify the resulting stepped-up alternating voltage.

nonthermal radiation—The radiation given off by energetic particles not in thermal equilibrium.

nontrip-free circuit breaker—A breaker that can be maintained closed by manual override action while a tripping condition persists.

nonuniform field—A field in which the scalar (or vector) at that instant does not have the same value at every point in a given region.

nonvolatile memory—1. A memory whose stored data is undisturbed by removal of operating power. 2. A type of computer system memory offering preservation of data storage during power loss or system shut-down. Magnetic-core read/write memory systems are typically nonvolatile and therefore do not require reloading to restore programs and data when system power is applied. *See also* volatile memory.

nonvolatile storage—1. Storage media that retain information in the absence of power and that will make the information available when power is restored. 2. A storage medium that retains its data in the absence of power.

nonwetting—A condition whereby a surface has contacted molten solder, but has had none of the solder adhere to it.

nonwirewound trimming potentiometer—A trimming potentiometer characterized by the continuous nature of the surface area of the resistance element to

be contacted. Contact is maintained over a continuous unbroken path. The resistance is achieved by using material compositions other than wire, such as carbon, conductive plastic metal film, and cement.

no-operation instruction—Also called blank instruction, waste instruction, or no-op. An instruction for a computer to do nothing but process the next instruction in sequence. *See also* skip.

NOR—1. A function of A and B that is true if both A and B are false. 2. Contraction of NOT-OR, the logical negation of the OR function. A NOR B is false if either A or B is true; true otherwise.

NOR device—1. A device that has its output in the logical 1 state if and only if all the control signals assume the logical 0 state. 2. An OR circuit that delivers an inverted output signal.

NOR element—A gate circuit having multiple inputs and one output that is energized only if all inputs are zero.

NOR gate—An OR gate followed by an inverter to form a binary circuit in which the output is logical 0 if any of the inputs is logical 1 and is logical 1 only if all the inputs are logical 0. With the opposite logic polarity, this type of gate is a NAND gate.

norm—1. The mean or average. 2. A customary condition or degree.

normal condition—The deenergized condition of a relay.

normal contact—A contact that in its normal position closes a circuit and permits current to flow.

normal distribution—1. The most common frequency distribution in statistics. The probability curve is bell-shaped, and the greatest probability occurs at the arithmetical average (i.e., at the top of the curve). The probability of occurrence of a particular value is shown by the areas between two abscissa values on the curve. *See also* Gaussian distribution. 2. A particular statistical distribution. For a distribution to be classified as a normal distribution, it must be unimodal—that is, most of the observations must fall fairly close to one mean—and symmetrical; that is to say, a deviation from the mean is as likely to be plus as it is likely to be minus. When graphed, the normal distribution takes the form of a bell-shaped curve.

normal electrode—A standard electrode used for measuring electrode potentials.

normal failure period—That period of time during which an essentially constant failure rate exists.

normal impedance—*See* free impedance.

normal induction—The limiting induction, either positive or negative, in a magnetic material that is under the influence of a magnetizing force that varies between two extremes.

normal induction curve—1. The curve obtained by plotting B (induction) against H (magnetizing force), starting from a totally demagnetized state. 2. The locus of the tips of a series of hysteresis loops, obtained by cycling the magnetizing force, H , in successively increasing steps. Nearly coincident with the initial magnetization curve.

normalization—The transforming of signals to a common basis—e.g., adjusting two signals, representing the same spoken word but differing in loudness, to the same loudness.

normalize—1. To adjust the representation of a quantity so that it lies within a prescribed range. 2. In a computer, to shift all digits of a word to the right or left to accommodate the maximum number of digits. 3. To divide a quantity (e.g., voltage, impedance, frequency) by a reference of the same dimension, thereby making the result dimensionless.

no-operation instruction — normal record level

normalized admittance—The reciprocal of normalized impedance.

normalized impedance—An impedance divided by the characteristic impedance of a waveguide.

normalized plateau slope—The slope of the substantially straight portion of the counting-rate-versus-voltage characteristic of a radiation counter tube, divided by the quotient of the counting rate and the voltage at the Geiger-Mueller threshold.

normal linearity—A manner of expressing linearity as the deviation from a straight line in terms of a given percentage of the output at a certain stimulus value, usually the full-scale value.

normally closed—Symbolized by nc. Designation applied to the contacts of a switch or relay when they are connected so that the circuit will be completed when the switch is not activated or the relay coil is not energized.

normally closed contact—Also called break contact. A contact pair that is closed when the coil of a relay is not energized.

normally closed switch—1. A switch that passes current until actuated. 2. A switch in which the contacts are closed when no external forces act on the switch.

normally high—A device in which the output is high in voltage in the rest condition.

normally low—A device in which the output is low in voltage in the rest condition.

normally open—Symbolized by no. Designation applied to the contacts of a switch or relay when they are connected so that the circuit will be broken when the switch is not activated or the relay coil is not energized.

normally open contact—A contact pair that is open when the coil of a relay is not energized.

normally open switch—1. A switch that must be actuated to pass current. 2. A switch in which the contacts are open (separated) when no external forces act on the switch.

normal mode—The expected or usual operating conditions, such as the voltage that occurs between the two input terminals of an amplifier.

normal-mode interference—Interference that appears between the terminals of a measuring circuit.

normal mode of vibration—A characteristic distribution of vibration amplitudes among the parts of the system, each part of which is vibrating freely at the same frequency. Complex free vibrations are combinations of these simple vibration forms.

normal-mode voltage—1. The actual signal voltage developed by a transducer. 2. The difference voltage between two input-signal lines.

normal operating period—The time interval between debugging and wear-out.

normal permeability—Ratio of the normal induction to the corresponding magnetizing force. In the cgs system, the flux density in a vacuum is numerically equal to the magnetizing force.

normal position—The position of the relay contacts when the coil is not energized.

normal propagation—The phenomenon of passing radio waves through space when atmospheric and/or ionospheric conditions are such as to permit the passage with little or no difficulty.

normal record level—In direct recording, the amount of record-head current required to produce 1 percent third-harmonic distortion of the reproduced signal at the record-level set frequency. Such distortion must result from magnetic-tape saturation, not from electronic circuitry.

normal-stage punching—In a computer, a card-punching system in which only the even-numbered rows are punched on the British standard card.

north pole—1. The pole of a magnet that points toward the north magnetic pole of the earth. (The lines of force internal to a magnet are assumed to leave from its north pole.) 2. A pole that attracts the south-seeking pointer of a field compass.

Norton's theorem—The current in any impedance Z_R , connected to two terminals of a network, is the same as though Z_R were connected to a constant-current generator whose generated current is equal to the current that flows through the two terminals when these terminals are short-circuited, the constant-current generator being in shunt with an impedance equal to the impedance of the network, looking back from the terminals in question.

NOT-AND circuit—An AND gating circuit that inverts the pulse phase.

notation—1. A manner of representing numbers. Some of the more important notation scales are as follows:

Base	Name
2	Binary
3	Ternary
4	Quaternary, tetral
5	Quinary
8	Octonary, octal
10	Decimal
12	Duodecimal
16	Hexadecimal, sexadecimal
32	Duotricenary
2.5	Biquinary

2. The act, process, or method of representing facts or quantities by a system or set of marks, signs, figures, or characters

notch—1. A rectangularly shaped depression that extends below the sweep line of the radar indicator in some equipment. 2. On a graph (a graph of frequency response, in particular), a point where a curve dips sharply and returns equally sharply to its original value.

notch antenna—An antenna that forms a pattern by means of a notch or slot in a radiating surface. Its characteristics are similar to those of a properly proportioned metal antenna and may be evaluated with similar techniques.

notch filter—1. An arrangement of electronic components designed to attenuate or reject a specific frequency band with sharp cutoff at either end. *See also* band-reject filter. 2. A band-elimination filter used to prevent the passage of specific frequencies. 3. A filter that attenuates a very narrow portion of the frequency spectrum, but will pass signals on either side. 4. A special filter, designed to reject a very narrow band of frequencies.

notch gate—The early and late gate display on the range CRT. It appears as a negative deflection of the range base line equal in width to the early and late gates.

notching—A term indicating that a predetermined number of separate impulses is required to complete operation of a relay.

notching circuit—A control circuit used in a cathode-ray oscilloscope to expand portions of the displayed image.

NOT circuit—Also called inverter circuit. A binary circuit with a single output that is always the opposite of the single input.

NOT device—A device that has its output in the logical 1 state if and only if the control signal assumes the logical 0 state. The NOT device is a single-input NOR device.

note—1. The pitch, duration, or both of a tone sensation. 2. The sensation itself. 3. The vibration causing the sensation. 4. The general term when no distinction is desired between the symbol, the sensation, and the physical stimulus. 5. A single musical tone. The notes of the musical scale are referred to by letters running alphabetically from A to G for the white keys. A black key may be called a sharp of the note below it or a flat of the note above it. Each note has a frequency exactly one-half that of the corresponding note in the next higher octave.

notebook computer—A personal computer that is easily portable and powered by a battery rather than an electrical current. Typical dimensions are "8½ × 11 × 2 to 4" thick.

NOT gate—1. An inhibitory circuit equivalent to the logical operation of negation (mathematical complement). The output of the circuit is energized only when its single input is not energized, and there will be no output if the input is energized. 2. A single-control device that evidences the appearance of a positive-pressure control signal with a single zero output signal. With no positive control signal, the zero NOT output signal ceases. A NOR gate with a single control connection performs as a NOT gate.

NOT majority—A logic function in which the output is false if more than half the number of inputs are true; otherwise the output is true.

noval base—A nine-pin glass base for a miniature electron tube. For orientation of the tube into its socket, the spacing between pins 1 and 9 is greater than between the other pins.

novar—A beam-power tube that has a nine-pin base.

novice license—A class of radiocommunication amateur license. Its requirements are the easiest of all, but novice operation is limited. Transmitters must be crystal controlled, and the maximum permissible plate input power is 75 watts. Novice licensees are restricted to certain frequencies (3.70–3.75, 7.15–7.20, 21.10–21.25, and 145–147 MHz, 222–225 MHz, 902–928 MHz, and 1.27–1.295 GHz).

noys—A measure of perceived noisiness; the noys scale is linear.

npin transistor—An npn transistor with a layer of high-purity germanium added between the base and collector to extend the frequency range.

npip transistor—An intrinsic-region transistor in which the intrinsic region is located between two p-regions.

n-plus-one address instruction—In a computer, a multiple-address instruction in which one address serves to specify the location of the next instruction of the normal sequence to be executed.

n+ type material—Heavily doped n-type material, formed by introducing donor impurities into a silicon substrate. Conduction takes place by the movement of free electrons.

npnp transistor—A hook transistor with a p-type base, n-type emitter, and a hook collector.

npn semiconductor—Double junction formed by sandwiching a thin layer of p-type material between two layers of n-type material of a semiconductor.

npn transistor—A transistor with a p-type base and an n-type collector and emitter. In construction, it consists of a thin layer of p-type semiconductor material sandwiched between two layers of n-type semiconductor material.

Symbol. Junctions.
npn transistor.

NPO—A commonly used code that is synonymous with EIA code COG. Both indicate a temperature characteristic of ± 30 ppm/ $^{\circ}\text{C}$ or less for a capacitor.

npo body (negative positive zero)—A designation referring to a class of capacitors in the temperature-compensating series that have an essentially nonvariant dielectric constant over a specified temperature range (commonly $+25^{\circ}\text{C}$ to $+85^{\circ}\text{C}$).

np semiconductor—Material in a region of transition between n- and p-type material.

N-quadrant—One of the two quadrants where the N-signal is heard in an A-N radio range.

n-region—Also called n-zone. The region where the conduction-electron density in a semiconductor exceeds the hole density.

NRZ—Abbreviation for nonreturn to zero. Data transmission and recording in which the transition represents the data, and the state remains unchanged until the next transition transmits more data on that line.

NRZI—Abbreviation for nonreturn-to-zero interchange. A recording technique using only negative and positive magnetic saturation states. Because NRZI does not use a neutral or unmagnetized state, usually called zero (0), there is never a return to zero in the recording. In the most common NRZI mode, a transition from one saturation to another coincides with a binary 1. No transition coincides with a binary 0.

ns—Letter symbol for nanosecond (10^{-9} s).

N-scan—See N-display.

N-scope—See N-display.

N-signal—A dash-dot signal heard in either a bisignal zone or an N-quadrant of a radio range.

NSOS—Same as PSOS (p-channel silicon gate devices), except it denotes n-channel devices.

n-terminal network—A network with n accessible terminals.

n th harmonic—A harmonic whose frequency is n times the frequency of the fundamental component.

NTSC—Abbreviation for National Television Standard Committee. The color system established in the United States and North America and adopted by numerous other countries. The field rate for NTSC is 60 Hz with 525 lines per screen, and the subcarrier transmission method is a straight phase- and amplitude-modulation system for chroma using a subcarrier frequency of 3.579545 MHz.

NTSC color bar pattern—The standard television test pattern of six adjacent color bars including the three primary colors plus their three complementary shades.

NTSC signal—A 3.579545-MHz (3.58-MHz) signal, the phase of which is varied with the instantaneous hue of the televised color, and the amplitude of which is varied with the instantaneous saturation of the color, as specified by the National Television System Committee.

NTSC triangle—1. On a chromaticity diagram, a triangle that defines the gamut of color obtainable through the use of phosphors. 2. The triangle in a chromaticity

diagram joining the chromaticities of the NTSC phosphors, and containing all chromaticities that can be produced by additive mixture of their light.

n-type—1. Refers to an excess of negative electrical charges in a semiconductor material. Natural silicon is made to be p-type by the addition of an acceptor impurity. 2. Semiconductor material whose impurities produce free electrons in the compound, leading to conduction.

n-type conductivity—The conductivity associated with conduction electrons in a semiconductor.

n-type crystal rectifier—A crystal rectifier in which forward current flows when the semiconductor is more negative than the metal.

n-type material—1. A crystal of pure semiconductor material to which has been added an impurity (an electron donor such as arsenic or phosphorous) so that its characteristics are altered and electrons serve as the majority charge carriers. 2. A quadrivalent semiconductor material, with electrons as the majority charge carriers, that is formed by doping with donor atoms.

n-type region—Portion of semiconductor material containing a small number of dopant atoms that have an extra (free) electron in their outer orbit. The n-region is a source of mobile negative charges.

n-type semiconductor—1. An intrinsic semiconductor in which the conduction-electron density exceeds the hole density. By implication, the net ionized impurity concentration is a donor type. 2. A semiconductor in which conduction is aided by the presence of more free electrons than holes. 3. Impurity semiconductor material containing a predominance of donor dopants, and in which conduction-band electrons normally form the principal current carriers. 4. A semiconductor material, such as germanium or silicon, with a small amount of impurity, such as antimony, arsenic, or phosphorous, added to increase the supply of free electrons. Such a material conducts electricity through the movement of electrons. 5. A semiconductor type in which the density of holes in the valence band is exceeded by the density of electrons in the conduction band. N-type behavior is induced by the addition of donor impurities, such as arsenic or phosphorus, to the crystal structure of silicon.

n-type semiconductor material—An extrinsic semiconductor material in which the conduction-electron density greatly exceeds the mobile-hole density.

nuclear battery—Also called an atomic battery. 1. A battery that converts nuclear energy into electrical energy. 2. Direct-conversion secondary cell or battery using radioisotopes as the energy source.

nuclear clock—A clock in which the time base is provided by the mean time interval between two successive disintegrations in a radioactive source.

nuclear magnetic resonance—The flipping over of a particle, such as a proton, as the result of the application of an alternating magnetic field at right angles to a steady magnetic field in which the particle is placed.

nucleation—The occurrence in an existing phase or state of a new phase or state.

nucleonics—The application of nuclear science in physics, chemistry, astronomy, biology, industry, and other fields.

nucleus—The core of an atom. It contains most of the mass and has a positive charge equal to the number of protons it contains. Its diameter is about one ten-thousandth that of the atom. Except for the ordinary hydrogen atom, the nuclei of all other atoms consist of protons and neutrons tightly locked together.

nude contact—A contact with a locking member that remains in the insert at all times.

null—1. A balanced condition that results in zero output from a device or system. 2. To oppose an output

that differs from zero so that it is returned to zero. 3. The minimum output amplitude (ideally, zero) in direction-finding systems in which the amplitude is determined by the direction from which the signal arrives or by the rotation in bearing of the system's response pattern. 4. In a computer, a lack of information, as opposed to a zero or blank for the presence of no information.

null balance—A condition in which two or more signals are summed and produce a result that is essentially zero.

null detection—A method of making DF measurements. The antenna is turned to the point where the received signal is weakest. The true bearing of the signal is then found by noting the antenna direction and using a correction factor.

null detector—1. An apparatus that senses the complete balance, or zero-output condition, of a system or device. 2. A circuit to detect when there is no current or when no voltage is present.

null-detector circuit—A circuit that determines when two circuits are in exact electrical balance, i.e., having the same voltages or currents.

null-frequency indicator—A device that indicates frequency by heterodyning two electrical signals together to give a zero beat indication.

null indicator—A device that indicates when current, voltage, or power is zero.

null method—Also called zero method. A method of measurement in which the circuit is balanced, to bring the pointer of the indicating instrument to zero, before a reading is taken (e.g., in a Wheatstone bridge, or in a laboratory balance for weighing purposes).

null modem—A device connecting two asynchronous adapters, thus enabling communications.

null-spacing error—In a resolver, the difference between 180° and the angle between null positions of the output winding with respect to one input winding.

number—An abstract mathematical symbol for expressing a quantity. In this sense, the manner of representing the number is immaterial. Take 26, for example. This is its decimal form but it could be expressed as binary 011010 and still mean the same. Some common numbering systems are binary (base 2), quinary (base 5), octonary or octal (base 8), and decimal (base 10).

number crunching—1. The act of performing complex numerical operations. 2. Refers to long or complex calculations. 3. Traditionally, using a computer for large or complex computational tasks; now applied to any task involving numbers.

number of overshoots—The total number of times that the transient response goes to a minimum or maximum value that is outside a specified range.

number of scanning lines—The ratio of the scanning frequency to the frame frequency.

number system—Any system for the representation of numbers. See also positional notation.

numeric—In computers, consisting entirely or partially of digits, as distinguished from alphabetic composition.

numerical analysis—1. The providing of convenient methods for finding useful solutions to mathematical problems and for obtaining useful information from available solutions that are not expressed in easily handled forms. 2. Methods for finding useful solutions to problems once they have been stated mathematically. Numerical analysis also studies errors that arise during calculations and how they may be kept within limits.

numerical aperture—Abbreviated NA. 1. A measure of the light-gathering capability of a fiber. Mathematically, it is expressed as the sine of one-half of the acceptance angle. 2. The characteristic of an optic conductor in terms of its acceptance of impinging light. Degree of openness, light-gathering ability, and angular acceptance are terms describing this characteristic. 3. A number that indicates a fiber's ability to accept light and shows how much light can be off-axis and still be accepted by the fiber. 4. A measure of the maximum acceptance angle for light propagation in an optical fiber; at angles larger than this there is no longer internal reflection.

$$NA = \sin \theta = \sqrt{(n_1^2 - n_2^2)}$$

where

θ = one-half of the input cone angle

n_1 = index of refraction of core

n_2 = index of refraction of cladding

numerical control—Abbreviated NC. 1. Descriptive of systems in which digital computers are used for the control of operations, particularly of automatic machines (e.g., drilling or boring machines, wherein the operation control is applied at a discrete point in the operation or process). Contrasted with process control, in which control is applied continuously. 2. The technique of controlling a machine or process through the use of command instructions in coded numerical form. 3. Controlling a machine or process by means of digitally encoded numeric data. The control information can be prerecorded, or the equipment can be under the direct control of a computer. 4. A technique whereby prerecorded information in symbolic form represents the complete instructions for the operation of a machine. 5. The use of a dedicated controller to direct the operations of a machine tool.

numerical control system—A system controlled by direct insertion of numerical data at some point. The system must automatically interpret at least some portion of the data.

numerical data—Data expressed in terms of a set of numbers or symbols that can assume only discrete values or configurations.

numerical-readout tube—A gas-filled cold-cathode digital-indicator tube having a common anode and containing stacked metallic elements in the form of numerals. When a negative voltage is applied to one of them, the element then becomes the cathode of a simple gas-discharge diode.

numerical coding—1. A system of abbreviation used in the preparation of information for machine acceptance in which all information is reduced to numerical quantities, in contrast to alphabetic coding. 2. System of coding, with digits as code characters, used in preparing information for input to a computer.

nutating feed—In a tracking radar, an oscillating antenna feed that produces an oscillating deflection of the beam without changing the plane of polarization.

nutating field—The time-variant, three-dimensional field pattern of a directional or beam-producing antenna having a nutating feed.

nuvistor—An electron tube in which all electrodes are cylindrical and are closely spaced, one inside the other, in a ceramic envelope.

nV—Letter symbol for nanovolt.

***Nuvistor.***

***n*-variable cube**—*See n*-cube.

nW—Letter symbol for nanowatt.

nybble—*See* nibble.

nylons—Family of polymers with outstanding toughness and wear resistance, low coefficient of friction, excellent electrical properties, and chemical resistance.

Nyquist diagram—A plot, in rectangular coordinates, of the real and imaginary parts of factor $\mu\beta$ for frequencies from zero to infinity in a feedback amplifier—where μ is the amplification in the absence of feedback, and β is the fraction of the output voltage superimposed on the amplifier input.

Nyquist interval—The maximum separation in time that can be given to regularly spaced instantaneous samples of a wave of a given bandwidth for complete determination of the waveform of the signal. Numerically it is equal in seconds to one-half the bandwidth.

Nyquist rate—Of a channel, the maximum rate at which independent signal values can be transmitted over the specified channel without exceeding a specified amount of mutual interference.

Nyquist theorem—A theorem that states that if a continuous bandwidth-limited signal contains no frequency components higher than f_c , then the original signal can be recovered without distortion if it is sampled at a rate of at least $2f_c$. This theorem applies to A/D converter applications as well as data transmission density over limited-bandwidth channels. *See also* sampling theorem.

***n*-zone**—*See n*-region.

O

OAO—Abbreviation for Orbiting Astronomical Observatory.

object—A data element that provides a well-defined external visibility but no insight into its internal structure.

object code—1. The output of an assembler or compiler that will execute on the target processor. Linking and loading may be required before this code can execute directly on the processor. 2. Machine-language instructions that are actually executed by a computer system. They are produced by a compiler from an application program written in a higher-level language. 3. A series of binary 1s and 0s that can be used by a computer directly.

object computer—The computer of the receiving end of a communication attempt such as a fax or modem.

object language—The computer language in which the output from a compiler or assembler is expressed.

object module—1. A module that serves as the output of an assembler or compiler and the input to a linkage editor. 2. An object program plus the control information a computer needs to load it and combine it with other object programs.

object-oriented programming—A programming environment in which symbols called objects communicate by passing messages. This approach permits the simulation of multiple unrelated, but simultaneously occurring, processes.

object program—1. A computer program that is the output of an automatic coding system. The object program may be a machine-language program ready for execution, or it may be in an intermediate language. 2. The binary form of a source program produced by an assembler or a compiler. The object program is composed of machine-coded instructions that the computer can execute. 3. The machine-language program that a compiler produces from the programmer's source program in high-level language. It is the one program that the computer actually executes. 4. A set of problem-solving machine-language instructions obtained through the compilation or assembly of the related source program.

oblique-incidence transmission—Transmission by means of a radio wave that travels obliquely up to the ionosphere and down again.

Oboe—A radar navigation system consisting of two ground stations that measure the distance to an airborne transponder beacon and relay this information to the aircraft.

obsolescence-free—Not likely to become outdated within a reasonable time.

occlude—To absorb; e.g., some metals will occlude gases, which must be driven out before the metals can be used in the electrodes or supports of a vacuum tube.

occluded contaminants—Contaminants that have been absorbed by a material.

occluded gas—Gas that has been absorbed by a material (e.g., by the electrodes, supports, leads, and insulation of a vacuum tube).

occupied bandwidth—1. The frequency bandwidth such that, below its lower and above its upper frequency limits, the mean powers radiated are each equal to 0.5 percent of the total mean power radiated by a given emission. 2. The band of frequencies that a given emission type uses.

OCR or ocr—Abbreviation for optical character recognition 1. A technology that enables a machine to automatically read and convert typewritten, machine-printed, mark-sensed, or hand-printed characters into electrical impulses for processing by a computer. OCR devices are designed to read man-readable data and convert it directly to a computer language. 2. The machine recognition of printed or written characters based on inputs from photoelectric transducers. 3. A device or scanner that can read printed or typed characters and convert them into a digital signal for input into a data or word processor. OCR units in word processing applications usually read special machine-readable type fonts. 4. A mechanized method of collecting data involving the reading of hand-printed or special-character fonts. If hand-written, the information must adhere to predefined rules of size, format, and location on the form.

octal—1. A numbering system based on 8 and using the digits 0 through 7. Since 8 is a power of 2, binary programs are easily converted into octal. Binary 11010110 (decimal 214) is written in octal as 326. 2. *See* notation. 3. Pertaining to a characteristic or property involving a selection, choice, or condition in which there are eight possibilities.

octal base—An eight-pin tube base (although unneeded pins are often omitted without changing the position of the remaining pins). An aligning key in the center of the base assures correct insertion of the tube into the socket.

octal, binary coded—Pertaining to a binary-coded number system with the radix 8, in which the natural binary values of 0 through 7 are used to represent octal digits with values from 0 to 7.

octal debugging technique—Also called online debugging technique (ODT). A system program designed to help the user debug object programs interactively. All addresses, registers, and memory location contents are expressed in octal notation. Letters and symbols make up the command set for ODT.

octal digit—One of the symbols 0, 1, 2, 3, 4, 5, 6, and 7 when used in numbering in the scale of 8.

octal fraction—A shorthand expression of the binary contents of a half word.

octal fractional—A quantity less than a whole number referenced to a numbering system that has the radix eight.

octal loading program—A computer utility program with provision for making changes in programs and tables that are in core memory and drum storage, reading in words that are coded in octal notation on punched cards or tapes.

octal numbering system—A numbering system based on powers of 8. This system is used extensively in computer work because it is derived simply from binary numbering.

octal plug—An eight-pin male connector with a locating key for proper orientation.

octave—1. The interval between two sounds having a basic frequency ratio of 2; by extension, the interval between any two frequencies having a ratio of 2:1. 2. A reference point for frequency or pitch; e.g., an 880-Hz tone is one octave higher than a 440-Hz tone and one octave lower than a 1760-Hz tone. An increase of one octave doubles the frequency. Dropping one octave reduces the frequency by one-half.

octave band—A band of frequencies whose limits have the ratio 2:1.

octave-band pressure level—Also called octave pressure level. The pressure level of a sound for the frequency band corresponding to a specified octave.

octave pressure level—See octave-band pressure level.

octode—An eight-electrode electron tube containing an anode, a cathode, a control electrode, and five additional grids.

octonary—See notation.

octonary signaling—A mode of communication in which information is represented by the presence and absence, or plus and minus variations, of eight discrete levels of a parameter of the signaling medium.

odd-even check—An automatic computer check in which an extra digit is carried along with each word to determine whether the total number of 1s in the word is odd or even, thus providing a check for proper operation. See parity check.

odd harmonic—Any harmonic whose frequency is the fundamental frequency multiplied by an odd number. The odd harmonics of 60 Hz are 180 Hz, 300 Hz, 420 Hz, etc.

odd-line interlace—The double-interlace system in which, since there are an odd number of lines per frame, each field contains a half line. In the 525-line television frame used in the United States, each field contains 262.5 lines.

odograph—Automatic electronic map tracer used in military vehicles for map making and land navigation. It automatically plots, on an existing map or on cross-sectional paper, the exact course taken by the vehicle. This is done by phototubes and thyratrons, which transfer the indication of a precision magnetic compass onto a plotting unit actuated by the speedometer drive cable. A pen then traces the course.

ODT—See octal debugging technique.

Oe—Letter symbol for oersted.

oersted—In the cgs electromagnetic system, the unit of magnetizing force equal to $1000/4\pi$ ampere-turns per meter. At any point in a vacuum, the magnetic intensity in oersteds is equal to the force in dynes exerted on a unit magnetic pole at that point. Letter symbol: Oe.

off bond—Bond that has some portion of the bond area extending off the bonding point.

off-center display—A PPI display whose the center does not correspond to the position of the radar antenna.

off-delay—A circuit that retains an output signal some definite time after the input signal is removed.

off-delay timers—A reset timer that is started by the opening of a circuit. Does not reset on power interruption.

octal loading program — off-normal contacts

off-ground—The voltage above or below ground at which a device is operated.

offhook or off-hook—1. A condition that occurs when the telephone handset is lifted from its mounting, thus causing the hookswitch to operate (close) and closing the loop to the central office. The offhook condition indicates a busy condition to incoming calls. 2. The signal that is sent to the central office, i.e., loop closed, current flowing as a result of the offhook condition. 3. The condition that indicates a closed loop or the active state of a telephone customer's line. 4. A modem automatically answering a call on the dial network is said to go off-hook. The opposite condition is on-hook.

offhook service—Priority telephone service in which a connection from caller to receiver is afforded by removing the phone from its cradle or hook.

office code—The first three digits of a seven-digit telephone number assigned to a subscriber.

off-limit contacts—Contacts on a stepping relay used to indicate that the wiper has reached the limiting position on its arc and must be returned to normal before the circuit can function again.

offline—1. Not physically connected to or using a communications medium. 2. The condition in which a user, terminal, or other device is not connected to a computer or is not actively transmitting via a network. Opposite of online. 3. Pertaining to equipment or devices not under direct control of the central processing unit. May also be used to describe the terminal equipment that is not connected to a transmission line. 4. Describing a communication system that has no direct connection between the communication line and the device which originates the message. 5. Disconnected from the computer system. 6. Equipment or devices in a system that are not under the direct control of the system.

offline cipher—Method of encryption that is not associated with a particular transmission system and in which the resulting cryptogram can be transmitted by any means.

offline equipment—Peripheral equipment that is not in direct communication with the computer central processing unit.

offline operation—1. A control system in which the computer does not respond immediately or directly to the events of the controlled process; some time may elapse between the occurrence of an event and the reaction of the computer to it. 2. In a computer system, operation of peripheral equipment independent from the central processor, e.g., the transcribing of magnetic tape information to printed form. 3. Operation performed while the computer is not engaged in monitoring or controlling a process or operation. 4. Data-processing operation that is handled outside of the regular computer program. For example, the computer could generate a magnetic tape, which would then be used to generate a report offline while the computer was doing another job.

offline system—1. A kind of teleprocessing system in which there must be human operations between the original recording functions and the ultimate data-processing function. 2. A system of processing information in which the data is submitted to some intermediate step (such as punched cards or magnetic tape) before it is processed by the computer.

offline unit—In a computer, the input/output device or auxiliary equipment not under direct control of the central processing unit.

off-normal contacts—Relay contacts that assume one condition when the relay is in its normal position and the reverse condition for any other position of the relay.

off-period—That portion of an operating cycle during which an electron tube or semiconductor is nonconducting.

offset—1. The measure of unbalance between halves of a symmetrical circuit. Generally caused by differences in transistor betas or in values of biasing resistors. 2. The change in input voltage necessary to cause the output voltage in a linear amplifier circuit to be zero. 3. In digital circuits, the dc voltage on which a signal is impressed. 4. The difference between the desired value or condition and the value or condition actually attained. 5. The voltage that must be applied between the inverting and noninverting inputs of an operational amplifier to cause the output voltage to go to zero. 6. A number that a computer adds to a base address to get a new effective address. 7. In a Hall-effect element, the output voltage at 0 gauss. 8. The difference between an amateur radio repeater's input and output frequencies. The offset on 2 meters is generally 600 kHz.

offset angle—In lateral-disc reproduction, the smaller of the two angles between the projections, into the plane of the disc, of the vibration axis of the pickup stylus and the line connecting the vertical pivot (assuming a horizontal disc) of the pickup arm with the stylus point.

offset binary—A natural binary code except that it is offset (usually $1/2$ scale) in order to represent negative and positive values. Maximum negative scale is represented to be all 0s while maximum positive scale is represented as all 1s. Zero scale (actually center scale) is then represented as a leading 1 and all remaining 0s.

offset current—1. The difference in current into the two inputs of an operational amplifier required to bring the output voltage to zero. 2. The difference between the two bias currents drawn by the inputs of a differential input stage of an electronic meter.

offset error—1. The error by which the transfer function fails to pass through the origin, referred to the analog axis. This is adjustable to zero in available analog-to-digital converters. 2. The analog value by which the transfer function of a D/A or A/D converter fails to pass through zero; it is generally specified in millivolts or in percent of full scale.

offset nulling—The adjustment of an external resistor in an operational amplifier circuit so that the output voltage is made zero when both input potentials are zero.

offset stacker—In a computer, a card stacker having the ability to stack cards selectively under machine control so that they protrude from the balance of the stack, thus giving physical identification.

offset voltage—1. The difference in voltage at the two inputs of an operational amplifier required to bring the output voltage to zero. 2. The deviation from zero output voltage of an amplifier having zero input voltage.

off-state—The condition of a thyristor corresponding to the portion of the principal characteristic between the origin and the breakpoint or points.

off-state current—The principal current when a thyristor is in the off state.

off-state voltage—The principal voltage when a thyristor is in the off state.

off-target jamming—Employment of a jammer away from the main units of the force. This is done to prevent the enemy from monitoring the jamming signals and using them to pinpoint the location of the force.

off-the-line supply—A supply in which raw dc is obtained by rectifying the line voltage directly without using an isolation transformer. Most switchers are off-the-line units.

OGO—Abbreviation for Orbiting Geophysical Observatory.

ohm—Symbolized by the Greek letter *omega* (Ω). 1. The unit of resistance. It is defined as the resistance, at 0°C, of a uniform column of mercury 106.300 cm long and weighing 14.451 grams. 2. The electrical resistance between two points of a conductor when a constant difference of potential of 1 volt, applied between these points, produces in this conductor a current of 1 ampere, the conductor not being the source of any electromotive force.

ohmic contact—1. Between two materials, a contact across which the potential difference is proportionate to the current passing through it. 2. A contact between two materials across which the voltage drop is the same regardless of the direction of current. 3. An electrical connection that passes current linearly in both directions. 4. In the context of semiconductor device design, a contact to a semiconductor crystal expressly designed so that it does not possess any of the unilateral properties of a normal metal semiconductor or p-type/n-type semiconductor junction. Usually all exterior electrode connections to a device chip are made by means of ohmic contacts.

ohmic heating—The energy imparted to charged particles as they respond to an electric field and make collisions with other particles. The name was chosen due to the similarity of this effect to the heat generated in an ohmic resistance due to the collisions of the charge carriers in their medium.

ohmic resistance—Resistance to direct current.

ohmic value—The resistance in ohms.

ohmmeter—A direct-reading instrument for measuring electric resistance. Its scale is usually graduated in ohms, megohms, or both. If the scale is graduated in megohms, the instrument is called a megohmmeter; if the scale is calibrated in kilohms, the instrument is a kilohmmeter.)

ohmmeter zero adjustment—In an ohmmeter, a potentiometer or other means of compensating for the drop in battery voltage with age. Usually a knob is rotated until the meter pointer is at zero on the particular scale being used.

Ohm's law—The voltage across an element of a dc circuit is equal to the current in amperes through the element, multiplied by the resistance of the element in ohms. Expressed mathematically as $E = IR$. The other two equations obtained by transposition are $I = E/R$ and $R = E/I$.

Ohm's law.

ohms per square—Also shown as ohms/square. 1. A unit of measurement of resistance by topological shape. A resistor topology can be considered to consist of continuous squares. The value of a resistor is equal to the number of squares times the ohms per square. 2. A unit of measure for thin- and thick-film resistors. The value of a film resistor depends on the sheet resistivity (ohms per square) and the aspect ratio (length to width). Resistors of different sizes but equal aspect ratios will have the same value. 3. The unit of sheet resistance or, more properly, of sheet resistivity.

ohms per square per mil—The unit of sheet resistivity. *See* sheet resistivity.

ohms per volt—A sensitivity rating for voltage-measuring instruments (the higher the rating, the more sensitive the meter). On any particular range, it is obtained by dividing the input resistance of the instrument (in ohms) by the full-scale voltage value of that range.

oil circuit breaker—A circuit breaker in which the interruption occurs in oil to suppress the arc and prevent damage to the contacts.

oiled paper—Paper that has been treated with oil or varnish to improve its insulating qualities.

oil-filled cable—Paper-insulated, lead sheathed cable into which high-grade mineral oil is forced under pressure, saturating the insulation. Main object is to prevent moisture and gases from entering. Also, it is easier to detect flaws due to leakage, as the oil is kept under constant pressure at all times.

oil fuse cutout—An enclosed fuse cutout in which all or part of the fuse support is mounted in oil.

oil-immersed forced-oil-cooled transformer (class FOA or FOW)—A transformer having its core and coils immersed in oil and cooled by the forced circulation of its oil through an external heat exchanger. If the heat exchanger utilizes forced circulation of air, the transformer is class FOA; if it utilizes forced circulation of water, the transformer is class FOW.

oil-immersed self-cooled/forced-air-cooled transformer (class OA/FA)—A transformer having its core and coils immersed in oil and having a self-cooled rating with cooling obtained by the natural circulation of air over the cooling surface (class OA) and a forced-air-cooled rating with cooling obtained by the forced circulation of air over this same cooling surface (class FA).

oil-immersed self-cooled transformer (class OA)—A transformer having its core and coils immersed in oil, the cooling being effected by the natural circulation of air over the cooling surface. (Smooth tank surfaces are generally sufficient to cool small transformers, but for about 25 kVA and larger, a supplementary heat-dissipating surface is provided in the form of external fins, tubes, or tubular radiators.)

oil-immersed transformer—A transformer whose core and coils are immersed in oil.

oil-immersed water-cooled transformer (class OW)—A transformer having its core and coils immersed in oil, the cooling being effected by the natural circulation of oil over the water-cooled surface. The water-cooled surface is provided by water flowing through copper cooling coils immersed in the oil and located inside the main transformer tank, through which the oil flows by thermosiphon action.

oil switch—A switch in which the interruption of the circuit occurs in oil to suppress the arc and prevent damage to the contacts.

Omega—A long-range hyperbolic navigation system that transmits interrupted cw signals from which phase differences are extracted. Transmissions occur from two

or more locations on a single carrier frequency utilizing time-sharing techniques.

omnibearing—The bearing indicated by a navigational receiver on transmissions from an omnirange.

omnibearing converter—An electromechanical device that combines an omnirange signal with aircraft heading information to furnish electrical signals for operating the pointer of a radio magnetic indicator. *See also* omnibearing indicator.

omnibearing indicator—An omnibearing converter to which a dial and pointer have been added.

omnibearing line—One of an infinite number of straight, imaginary lines radiating from the geographical location of a VHF omnirange.

omnibearing selector—Instrument capable of being set manually to any desired omnibearing or its reciprocal in order to control a course-line deviation indicator.

omniconstant—A calculator that can add consecutively in any steps of any predetermined size, raising the power of any number in consecutive steps.

omnidirectional—Also called nondirectional. 1. All-directional; not favoring any one direction. Having no particular direction of maximum emission or sensitivity. An omnidirectional speaker is one that theoretically radiates equally in all directions. 2. Responding equally to sounds arriving from any direction. 3. Emitting sound equally in all directions. Frequently applied to speakers that are only "omni" in the forward or upward hemisphere.

omnidirectional antenna—Also called nondirectional antenna. 1. An antenna producing essentially the same field strength in all horizontal directions and a directive vertical radiation pattern. 2. An antenna that radiates or receives equally well in all directions in a horizontal plane.

omnidirectional hydrophone—A hydrophone having a response that is essentially independent of the angle of arrival of the incident sound wave.

omnidirectional microphone—Also called non-directional microphone. 1. A microphone that responds to a sound wave from almost any angle of arrival. 2. A microphone that picks up sound relatively evenly from all directions.

omnidirectional radio range—Radio aid to air navigation using a transmitter that radiates throughout 360° azimuth, providing aircraft with a direct indication of the bearing of the transmitter.

omnidirectional range—Also called omnirange. A radio facility providing bearing information to or from such facilities at all azimuths within its service area.

omnidirectional range station—In the aeronautical radionavigational service, a land station that provides a direct indication of the bearing (omnibearing) of that station from an aircraft.

omnigraph—An instrument that produces Morse-code messages for instruction purposes. It contains a buzzer circuit that is usually actuated by a perforated tape.

omnirange—*See* omnidirectional range.

OMR—Abbreviation for optical mark recognition.

on—Said of an electronic element that is conducting current.

on-board—Located on a circuit board. Most frequently refers to the motherboard of a computer.

on-call channels—Similar to allocated channels except that full-time exclusive use of the channel is not warranted.

on-course curvature—In navigation, the rate at which the indicated course changes with respect to the distance along the course path.

on-course signal—The monotone radio signal that indicates to the pilot that he is neither too far to the right nor to the left of the radio beam being followed.

on-delay—A circuit that produces an output signal some definite time after an input signal is applied.

on-demand system—A system from which the desired information or service is available at the time of request.

ondograph—An instrument for drawing alternating-voltage waveform curves. It employs a capacitor that is momentarily charged to the amplitude at a particular point on the curve and then discharged through a recording galvanometer. This is repeated at intervals of about once every hundred cycles, with the sample taken a little farther along on the waveform each time.

ondoscope—A glow-discharge tube used on an insulating rod to indicate the presence of high-frequency radiation near a transmitter. The radiation ionizes the gas in the tube, and the visible glow indicates the presence of radiation.

one-input terminal—Called the set terminal. The terminal which, when triggered, will put a flip-flop in the 1 (opposite of starting) condition.

one-line unit—In a computer, the input/output device or auxiliary equipment under direct control of the computer.

one-many function switch—A function switch in which only one input is excited at a time and each input produces a combination of outputs.

one output—See one state.

one-output terminal—The terminal that produces an output of the correct polarity to trigger a following circuit when a flip-flop circuit is in the 1 condition.

ones complement—1. Having to do with arithmetic that provides a method of negating a binary number so that binary subtraction can be performed with the techniques of addition. The ones complement of a binary number is obtained by complementing all bits in that number. In ones-complement addition, end-around carry must be used. 2. A binary digit that when added to another binary digit yields 1; the inverse binary state of any given bit.

ones-complement arithmetic—A binary arithmetic system in which negative numbers are created by inverting individual bits in the binary representation of the positive number.

one-shot—1. A circuit that produces an output signal of fixed duration when an input signal of any duration is applied. 2. See monostable. 3. A type of multivibrator that provides an output pulse of a specific length whenever it receives an input pulse. Often used to provide delays or stretch or expand pulses that are the wrong length or shape.

one-shot multivibrator—See monostable multivibrator.

one state—Also called one output. In a magnetic cell, the positive value of the magnetic flux through a specified cross-sectional area, determined from an arbitrarily specified direction. See also zero state.

one-third-octave band—A frequency band in which the ratio of the extreme frequencies is 1.2599.

one-to-partial-select ratio—In a computer, the ratio of a 1 output to a partial-select output.

one-to-zero ratio—In a computer, the ratio of a 1 output to the 0 output.

O-network—A network composed of four impedance branches connected in series to form a closed

circuit. Two adjacent junction points serve as input terminals, and the remaining two as output terminals.

one-way communication—Applied to certain radiocommunication or intercommunications systems in which a message is transmitted from one station to one or more receiving stations that have no transmitting apparatus.

one-way repeater—See repeater.

on-hook—1. A condition that exists when the telephone handset is on its mounting, thus keeping the hook-switch open. The on-hook condition opens the dc loop, indicating that calls can be accepted. 2. The signal that is sent to the central office (i.e., loop open, no current) as a result of the on-hook condition. 3. The condition that indicates the idle state or open loop of a telephone customer's line. A modem not in use is said to be on-hook.

online—1. Pertaining to a computer that is actively monitoring or controlling a process or operation, or to an operation performed by such a computer. 2. Pertaining to equipment or devices under direct control of the central processing unit. 3. Pertaining to a user's ability to interact with a computer. 4. Describes equipment or devices that are connected to the communications line. 5. A word or data processing operation that is performed on a local system connected to and sharing the facilities of a remote central processor. 6. The condition in which a user, terminal, or other device is actively connected with the facilities of a communications network or computer; opposite of offline. 7. Any equipment or process that sends information directly to a computer for immediate processing and immediate results is said to be online. This is in contrast with storing the information and having the computer process it later. 8. Pertaining to peripheral equipment or devices in direct communication with the central processing unit of a computer. May also be used to describe terminal equipment that is connected to a transmission line. 9. A direct connection between a remote terminal and a central processing site. 10. Refers to equipment or devices in a system that are directly connected to and under the control of the computer. 11. Physically connected to and using a communications medium or remote computer.

online computers—Incorporation of calculators or small computers into spectroradiometric systems to control wavelength intervals, wavelength ranges, and detector signals, and to produce computed absolute spectroradiometric values.

online data reduction—The processing of information as rapidly as the information is received by the computing system or as rapidly as it is generated by the source.

online debugging technique—See octal debugging technique.

online operation—1. An operation carried on within the main computer system (e.g., computing and writing results onto a magnetic tape, printed report, or paper tape). 2. Operation in which information concerning a controlled process is fed directly into a computer, and the computer exercises direct control on the basis of this information. Since the computer reacts without appreciable time lag, results are said to be in real time. 3. A type of system application in which the input data to the system

is fed directly from the measuring devices, and the computer results are obtained during the process of the event; e.g., a computer receives data from wind tunnel measurements during a run, and the computations of dependent variables are performed during the run, enabling a change in the conditions so as to produce particularly desirable results. 4. Operations in which the programmable controller is directly controlling the machine or process.

online processing—A data-processing approach in which transactions are entered into the computer directly as they occur.

online system—1. A teleprocessing system in which the input enters the computer directly from the originating point and/or in which the output is transmitted directly to the point at which it is used. 2. A telegraph system that involves transmitting directly into the system. 3. A system of processing information in which the input data enters the computer directly from, and the output data is transmitted directly to, its point of origin.

on-off control—A simple control system in a switch, in which the device being controlled is either fully on or fully off and no operating positions are available.

on-off keying—Keying in which the output of a source is alternately transmitted and suppressed to form signals.

on-off ratio—Ratio of the duration (on) of a pulse to the space (off) between successive pulses.

on-off switch—*See* power switch.

on-off tests—The switching of various suspected interference sources on and off while the victim receiver is monitored so that the actual source can be identified.

on period—That portion of an operating cycle during which an electron tube is conducting.

on state—The condition of a thyristor corresponding to the low-resistance low-voltage portion of the principal characteristic.

on-state current—The principal current when a thyristor is in the on state.

on-state voltage—The principal voltage when a thyristor is in the on state.

on the air—Transmitting.

on-the-fly—Recording techniques in which reading, writing, and block spacing require no tape stoppage. These techniques require total control over data transmission. For long-length recording, coordination between data supply and tape demand is essential.

on-the-fly printer—A high-speed line printer in which continuously rotating print wheels and fast-acting hammers are used so that the successive letters in a line of text are printed so rapidly that they appear to be printed simultaneously.

on voltage—The voltage with respect to ground or the minus supply at a switch output when it is in the conducting, or on, state.

opacimeter—Also called turbidimeter. A photoelectric instrument for measuring the turbidity (amount of sediment) of a liquid. It does this by determining the amount of light that passes through the liquid.

opacity—1. The degree of nontransparency of a substance—i.e., its ability to obstruct, by absorption, the transmission of radiant energy such as light. Opacity is the reciprocal of transmission. 2. The ratio of incident flux to transmitted flux. The inverse of transmission factor. 3. The characteristic of an object that prevents light from passing through.

opal lamp—A tungsten-filament lamp that uses an opal glass bulb to diffuse light.

op amp—Abbreviation for operational amplifier.

opaque—1. The optical quality of a substance whereby light cannot pass through it. The meaning is directly opposite to that of transparent. Thus, steel is

online processing — open collector output

opaque to visible light. 2. A term describing a substance that is impervious to light; the characteristic of a substance that has no luminous transmittance.

op code—Also opcode. Abbreviation for operation code.

open—1. A circuit interruption that results in an incomplete path for current (e.g., a broken wire, which opens the path of the current). 2. A break in the continuity of an electrical circuit that prevents current from flowing. 3. The computer command used to view a document or other file.

open architecture—1. A system (usually a computer) whose characteristics comply with industry standards and can be connected to other systems that also comply with these standards. 2. Computer design practices that encourage other manufacturers to develop supportive peripherals, software, and internal components. *Compare* closed architecture.

open-center display—A PPI display on which zero range corresponds to a ring around the center of the display.

open circuit—1. A circuit that does not provide a complete path for the flow of current. *See also* open. 2. A discontinuous electrical path or circuit through which no current can flow.

open-circuit impedance—The driving-point impedance of a line or four-terminal network when the far end is open.

open-circuit jack—A jack that has its through circuit(s) normally open. Circuits are closed by inserting mating plugs.

Open-circuit jack.

open-circuit parameters—The parameters of an equivalent circuit of a transistor that are the result of selecting the input current and output current as independent variables.

open-circuit signaling—Signaling in which no current flows under normal (i.e., inoperative) conditions.

open-circuit system—A system in which the sensors are connected in parallel. When a sensor is activated, the circuit is closed, permitting a current that activates an alarm signal.

open-circuit voltage—1. The voltage at the terminals of a battery or other voltage source when no appreciable current is flowing. 2. The voltage at the terminals of a voltage source when no current is being drawn from the source. 3. The voltage of a cell or battery under a no-load condition and measured with a high-impedance voltmeter.

open collector—A type of output structure found in certain bipolar logic families. The output is characterized by an active transistor pulldown for taking the output to a low voltage level and no pull-up device. Resistive pull-ups are generally added to provide the high-level output voltage. Open-collector devices are useful when several devices are to be used together on one I/O bus, such as the IEEE-488 bus.

open collector output—A feature of some semiconductor memories and other circuits that permits the formation of larger arrays by wiring several units together.

open core—A core fitting inside a coil but having an external return path. The magnetic circuit thus has a long path through air.

open-delta connection—Two single-phase transformers connected so that they form only two sides of a delta, instead of the three sides with three transformers in a regular delta connection.

open-ended—Pertaining to a system or process that is receptive to augmentation.

open-entry contact—1. A female contact designed for a certain size male pin, but having a spring construction that allows use of larger pins. 2. A female-opening contact unprotected from possible damage or distortion from a test probe or an oversized or misaligned male contact.

open-fuse cutout—An enclosed fuse cutout in which the fuse support and fuse holder are exposed.

open loop—1. Pertaining to a control system that does not provide self-correcting action for errors in the desired operational condition. 2. Having to do with an operational amplifier that does not have feedback. 3. An arrangement in which a computer monitors a process or device and presents the results in real time so that an operator can make adjustments to the process or operation, if required.

open-loop bandwidth—Without feedback, and frequency limits at which the voltage gain of the device drops off 3 dB below the gain at some reference frequency.

open-loop control system—A control system in which there is no self-correcting action, as there is in a closed-loop system.

open-loop differential voltage gain—*See* differential voltage gain.

open-loop gain—The ratio of the (loaded) output of an amplifier without any feedback to its net input at any frequency. Usually implies voltage gain.

open-loop output impedance—The complex impedance seen looking into the output terminals of an operational amplifier with no external feedback and in the linear-amplification region. In closed-loop operation, the output impedance is equal to the open-loop impedance divided by the loop gain. If the open-loop impedance is not more than a few hundred ohms and the loop gain is high enough for good gain accuracy and stability, the closed-loop impedance will be on the order of an ohm or less, which can be neglected in most applications.

open-loop output resistance—The resistance looking into the output terminal of an operational amplifier operating without feedback and in the linear-amplification region.

open-loop system—A control system that does not have a means of comparing input and output for control purposes.

open-loop voltage gain—The ratio of the output signal voltage of an operational amplifier to the different input signal voltage producing it with no feedback applied.

open magnetic circuit—A magnet that has no closed external ferromagnetic circuit and does not form a complete conducting circuit itself (e.g., a permanent magnet ring interrupted by an air gap).

open motor—A motor having ventilating openings that permit passage of external cooling air over and around the windings of the machine. When such motors have an internal fan to aid the movement of ventilating air, they may be referred to as self-ventilated.

open-phase protection—The effect of a device operating on the loss of current in one phase of a polyphase circuit to cause and maintain the interruption of power in the circuit.

open-phase relay—A relay that functions when one or more phases of a polyphase circuit open and sufficient current is flowing in the remaining phase or phases.

open plug—A plug designed to hold jack springs in their open position.

open-reel—Also called reel-to-reel. Used to designate any tape format in which the running tape is wound onto a separate takeup reel. As distinguished from cartridges and cassettes, where the takeup reel is either nonexistent (cartridge) or is included in the tape package (cassette).

open relay—A relay not having an enclosure.

open repeater—A repeater whose access is not limited.

open routine—In a computer, a routine that it is possible to insert directly into a larger routine without a linkage or calling sequence.

open subroutine—Also called direct-insert subroutine. 1. A subroutine inserted directly into a larger sequence of instructions. Such a subroutine is not entered by a jump instruction; hence, it must be recopied at each point where it is needed. 2. In a computer, a separately coded sequence of instructions that is inserted in another instruction sequence directly in the line of flow.

open system—A computer processor or set of connected processors for which standards are published, thus allowing an application running in the system to communicate with other applications in the same or other systems.

open temperature pickup—A temperature transducer in which its sensing element is directly in contact with the medium whose temperature is being measured.

open wire—1. A conductor separately supported above the earth's surface. 2. Communication lines that aren't insulated and formed into cables, but are instead mounted on aerial crossarms on utility poles.

open-wire circuit—A circuit made up of conductors separately supported on insulators.

open-wire loop—The branch line on a main open-wire line.

open-wire transmission line—A transmission line formed by two parallel wires. The distance between them, and their diameters, determines the surge impedance of the transmission line.

operand—1. The quantity that is affected, manipulated, or operated on. It may be a number, a string, an address, etc. 2. Any of the quantities arising out of or resulting from the execution of a computer instruction. An operand can be an argument, a result of computation, a constant, a parameter, the address of any of these quantities, or the next instruction to be executed.

operate current—The minimum current required to trip all the contact springs of a relay.

operate time—1. The time that elapses, after power is applied to a relay coil, until the contacts being checked have operated (i.e., first opened in a normally closed contact, or first closed in a normally open contact). 2. The phase of computer operation during which an instruction is being executed.

operate-time characteristic—The relation between the operate time of an electromagnetic relay and the operate power.

operating angle—The electrical angle (portion of a cycle) during which plate current flows in an amplifier or an electronic tube. Class A amplifiers have an operating angle of 360°; class B, 180° to 360°; and class C, less than 180°.

operating code—Abbreviated opcode or op code. Source statement that generates machine codes after assembly.

operating conditions—Those conditions, excluding the variable measured by the device, to which a device is subjected.

operating cycle—The complete sequence of operations required in the normal functioning of an item of equipment.

operating frequency—The rated ac frequency of the supply voltage at which a device is designed to operate.

operating life—The minimum length of time over which the specified continuous and intermittent rating of a device, system, or transducer applies without change in performance beyond the specified tolerance.

operating-mode factor—A failure-rate modifier determined by the type of equipment environment, e.g., laboratory computer, nose-cone compartment, etc.

operating overload—The overcurrent to which electric apparatus is subjected in the course of the normal operating conditions that it may encounter.

operating point—Also called quiescent point. On a family of characteristic curves of a vacuum tube or transistor, a point whose coordinates describe the instantaneous electrode voltages and currents for the operating conditions under consideration.

operating position—The operator-attended terminal of a communications channel. It is usually used in a singular sense (e.g., a radio-operator's position, a telephone-operator's position), even when there is no more than one operating position.

operating power—The power actually reaching a transmitting antenna.

operating range—*See* receiving margin.

operating ratio—*See* availability, 1.

operating system—Also called a disk operating system. 1. Software that controls the carrying out of computer programs and that may provide scheduling, debugging, input/output control, accounting, compilation, storage assignment, data management, and related services. 2. The totality of software that describes the methods by which data is processed to obtain a desired result. 3. A collection of software that schedules jobs; assigns resources, such as peripherals; manages all data transfers between the computer and its peripherals; assigns places in memory to programs and data; processes interrupts; and performs various housekeeping functions. 4. A structured set of software routines whose function is to control the execution sequence of programs running on a computer, supervise the input/output activities of these programs, and support the development of new programs through such functions as assembly, compilation, editing, and debugging. 5. A collection of system software that permits user-written tasks to interface to the machine hardware and interact with other tasks in a straightforward, efficient, and safe manner. 6. An integrated collection of supervisory routines (usually user-transparent) responsible for allocation of system resources among user tasks. These routines may include memory management, I/O handling, logging, storage assignment, operator interaction, and job scheduling. Every operating system is different in what services it provides and the way in which the services are implemented. Programs written for one operating system won't normally run under other operating systems.

operating temperature—The temperature or range of temperatures at or over which a device is expected to operate within specified limits of error.

operating temperature range—The interval of temperatures in which a component device or system is intended to be used, specified by the limits of this interval.

operating time—The time period between turn-on and turn-off of a system, subsystem, component, or part

during which the system, etc., functions as specified. Total operating time is the summation of all operating-time periods.

operating voltage—1. The direct voltage applied to the electrodes of a vacuum tube under operating conditions. 2. The voltage at which a circuit element operates. 3. The voltage of the system on which a device is operated.

operation—1. In mathematics, the determination of a quantity from two or more other quantities according to some rule. Examples are addition and multiplication in conventional arithmetic, and the AND and OR operations in Boolean algebra. 2. A specific action that a computer will perform whenever an instruction calls for it (e.g., addition, division).

operational amplifier—Also called op amp. 1. An amplifier that performs various mathematical operations. Application of negative feedback around a high-gain dc amplifier produces a circuit with a precise gain characteristic that depends on the feedback used. By the proper selection of feedback components, operational amplifier circuits can be used to add, subtract, average, integrate, and differentiate. An operational amplifier can have a single-input-single-output, differential-input-single-output, or differential-input-differential-output configuration. 2. Generally, any high-gain amplifier whose gain and response characteristics are determined by external components. 3. An exceptionally versatile linear amplifier (usually a linear IC) used extensively in control, computation, and measurement applications. 4. A stable, high-gain, direct-coupled amplifier that depends on external feedback from the output to the input to determine its functional characteristics. The term operational is derived from the fact that the first op amps were employed to perform addition, multiplication, division, integration, and differentiation, among other mathematical operations, in analog computers. 5. An active device characterized by high input impedance and very high voltage gain. Operational amplifiers generally have a differential input and a single-ended output. 6. A device having power gain down to zero frequency, for use in a feedback loop. It manipulates an output variable or variables in response to a local input variable or variables derived from an associated characterizing structure. This is done so as to enforce a prescribed functional relationship between one such output variable and a set of variables supplied to that structure, through reducing the local input variable or variables substantially to null or to equality. 7. An active, direct-coupled electrical subsystem having power gain, for use in a feedback circuit. In response to local input voltages or currents derived from an associated characterizing network, it manipulates an output voltage or current so as to enforce a prescribed functional relationship between a related output voltage or current and a set of currents or voltages supplied to that network, through bringing about a substantial balance. 8. A dc amplifier that has high gain, wide bandwidth, low noise, and low output impedance that can be combined with a passive network to provide an active analog device.

operational differential amplifier—An operational amplifier that utilizes a differential amplifier in the first stage.

operational readiness—The probability that, at any point in time and under stated conditions, a system will be either operating satisfactorily or ready to be placed in operation.

operational reliability—*See* achieved reliability.

operational transconductance amplifier—Abbreviated OTA. A device similar to a conventional operational amplifier, but with a current output and a

means for controlling transconductance with a current input.

operation code— Also called op code, the operation part of an instruction, or a command. 1. The part of a machine language instruction or assembly language instruction specifying the operation to be performed. The other segments specify the registers, address, or input/output ports. (In the microprocessor world, the op code includes the first 8 bits.) 2. The list of operation parts occurring in an instruction code, together with the names of the corresponding operations (e.g., add, unconditional transfer, add and clear, etc.). 3. That part of a computer instruction word that designates the function performed by a given instruction (e.g., the op codes for arithmetic instructions include ADD, SUB, DIV, and MUL). 4. The symbols within an instruction that represent the particular operation to be performed (e.g., add). 5. The portion of an instruction which designates the operation to be performed by a computer (e.g., add, subtract, or move). 6. A code signifying a particular task to be done by the computer.

operation decoder— In a computer, circuitry that interprets the operation-code portion of the machine instruction to be executed and sets other circuitry for its execution.

operation number— In a computer, a number that designates the position of an operation or its equivalent subroutine in the sequence of operations that makes up a routine. A number that identifies each step in a program stated in symbolic code.

operation part— In a computer instruction, the part that specifies the kind of operation, but not the location of the operands. *See also* instruction code.

operation register— In a computer, the register that stores the operation-code portion of an instruction.

operations research— 1. The solving of large-scale or complicated problems that arise from an operation in which a major decision must be based on solutions of relationships involving a large number of variables. 2. The development and application of quantitative techniques to the solution of problems faced by managers of public and private organizations. More specifically, theory and methodology in mathematics, statistics, and computing are adapted and applied to the identification, formulation, solution, validation, implementation, and control of decision-making problems.

operation time— The amount of time required by a current to reach a stated fraction of its final value after voltages have been applied simultaneously to all electrodes. The final value is conventionally taken as that reached after a specified length of time.

operator— 1. Any person who operates, adjusts, and maintains equipment—specifically, a computer, radio transmitter, or other communications equipment. 2. A symbol that designates a mathematical operation, such as +, ×, etc.

operator license— The instrument of operator authorization, including the class of operator privileges.

opposition— The phase relationship between two periodic functions of the same period when the phase difference between them is half of a period.

optical ammeter— An electrothermic instrument for measuring the current in the filament of an incandescent lamp. It normally uses a photoelectric cell and indicating instrument to compare the illumination with that produced by a current of known magnitude in the same filament.

optical axis— 1. The Z-axis of a crystal. 2. The straight line passing through the centers of the curved surfaces of a lens or lens system.

optical bar-code reader— A device used with the data station to read coded information from particular documents at the rate of hundreds of characters per second.

optical character— A printed character, frequently used in utilities billing, that can be read by a machine without the aid of magnetic ink.

optical character reader— Abbreviated OCR. 1. A photoelectric device that scans printed or typed copy and produces electrical signals that allow recognition and/or reproduction of the copy being scanned. 2. A photosensitive device used to read numerical data at a rate of up to 480 characters per second.

optical character recognition— Identification of printed characters by a machine using light-sensitive devices. *See also* OCR.

optical communication cable— Fiber with a protective jacket around it. A cable may have one or more fibers within it. *See* optical communication fiber.

optical communication fiber— A term analogous to a single strand of electrical wire in that it carries information from point to point. *See* optical communication cable.

optical communications— 1. Communications through the use of beams of visible, infrared, or ultraviolet radiation, or, over much longer distances, through the use of laser beams. *See also* coherent light communications. 2. The transmission and reception of information by optical devices and sensors. *See also* lightwave communications.

optical conductors— In fiber optics, materials that offer a low optical attenuation to transmission of light energy. Types of optical conductors include the following: (a) single fiber—a discrete optical conductor; (b) bundle—a number of optical conductors in a random arrangement, grouped together and used as a single transmission medium (channel); (c) single-channel, single-bundle cable—a bundle of optical conductors with a protective covering; (d) multichannel, single-fiber cable—more than one single-fiber cable jacketed; (e) single-channel, single-fiber cable—a discrete optical conductor with a protective covering; (f) multichannel bundle cable—more than one single-bundle cable jacketed; and (g) multichannel cables—a combination of cables.

optical coupler— Also called optoisolator, optical isolator, photocoupler, or optocoupler. A device designed to transfer electrical signals by utilizing light waves to provide coupling with electrical isolation between input and output. A typical optical coupler uses a light-emitting diode (LED) to convert the electrical signal of the primary circuit into light and a phototransistor in the secondary circuit to reconvert the light signal back into an electrical signal.

Optical coupler for solid-state relay.

optical coupling—Sometimes called crosstalk. In fiber optics, light leakage from one fiber to another by evanescent boundary wave interaction.

optical cropper—A mechanical or electrical electromagnetic device for passing and then interrupting a beam of light for a known brief interval. Examples include tuning forks, rotation shutters, and the more sophisticated Kerr cells.

optical damping—A damping ratio slightly less than unity in which the overshoot is less than the specified uncertainty of the instrument.

optical data link—A system consisting of a transmitter (i.e., a light source), a fiber-optic cable, and a receiver (i.e., a photodetector), connected together in such a manner that light waves from the source can be received at the receiver. Light from the transmitter is usually modulated by an intelligence-bearing signal.

optical density—The negative logarithm of the percent transmittance (or reflectance) of a transparent (or opaque) material.

optical detector—A device used in optical fiber communication systems, such as CATV and data links, for optical fiber measurements, to combine or split optical signals at desired ratios by insertion into a transmission line; for example, a three-port or four-port unit with precise connectors at each port to enable inputs to be coupled together and transmitted via multiple outputs.

optical disk—A very-high-density information storage medium that uses light to read and write digital information.

optical distortion—An aberration of spherical surface optical systems due to the variation in magnification with distance from the optical axis.

optical encoder—A device designed to accurately measure linear or rotary motion by detection of the movement of markings on a transparent medium past a fixed point of light. The encoder has a moving code plate, a glass disk with positional or angular information on it—generally bit information—and simple geometric optics for readout.

Optical encoder.

optical end-finish—The surface condition at the face of an optical conducting medium.

optical fiber—1. An optical waveguide. 2. A core of transparent material surrounded by a transparent cladding that has a lower refractive index. Both core and cladding are usually made of glass. Because of this arrangement, light rays launched into the fiber are restricted by total internal reflection and are thus confined within the core. 3. A single discrete optical transmission element, usually consisting of a fiber core and a fiber cladding. As a light-guidance system (dielectric waveguide) that is usually cylindrical in shape, it consists either of a cylinder of transparent dielectric material of given refractive index whose walls are in contact with a second dielectric material of a lower refractive index, or of a cylinder whose core has a refractive index that gets progressively lower away from the center. The length of a fiber is usually much greater than its diameter. The fiber relies on internal reflection to transmit light along its axial length. Light enters one end of the fiber and emerges from the opposite end with losses dependent on length, absorption, scattering, and other factors. A bundle of fibers has the ability to transmit a picture from one of its surfaces to another, around curves, and into otherwise inaccessible places with an extremely low loss of definition and light, by the process of total internal reflection. Each fiber transmits only one element of the composite emergent image. As the definition in the output image depends on the smallness of each element composing it, it is desirable to keep the cross section of the individual fibers as small as possible. If the spacing of the fibers increases toward the output end of the bundle, the image is magnified; if spacing is reduced, the image is reduced in size. By crossing the fibers systematically or randomly, the image is scrambled and can be recovered by retransmitting the scrambled image backward through the same or equivalent fiber bundle. 4. A cylinder or core of transparent dielectric material surrounded by a second dielectric. In order to propagate light, the refractive index of the core material is greater than that of the surrounding cladding material. To obtain satisfactory optical isolation of the core, the cladding material has a minimum thickness of one or two wavelengths of the light transmitted.

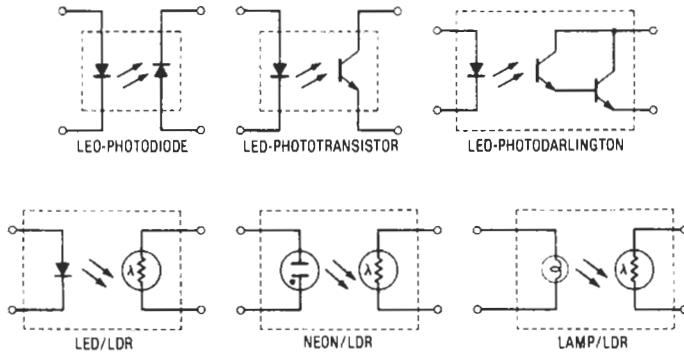

optical fiber bundle—Many optical fibers in a single protective sheath or jacket. The jacket is usually polyvinyl chloride (PVC). The number of fibers could range from a few to several hundred, depending on the application and the characteristics of the fibers.

optical horizon—The locus of points at which straight lines extended from a given point are tangent to the surface of the earth.

optical isolator—A photon-coupled device in which an electrical signal is converted into light that is projected through an insulating interface and reconverted to an electrical signal. *See also* optical coupler; optoisolator.

Optical fiber link.

Optical isolator.

optical mark recognition—Abbreviated OMR. An information-processing technology that converts data into another medium for computer input. This is accomplished by the presence of a mark in a given position, each position having a value known to the computer and which may or may not be understandable to humans.

optical maser—See laser.

optical memory—The direct storage of data as bits in memory using optical systems and properties. The memory makes use of a laser beam that is divided by a beam splitter and controlled by a modulator and a deflector to transpose bits into a given area of storage in memory. On the other side of the memory plane, a laser and a deflector read the memory, bit by bit, the bits being read by a scanning photodetector. Erasure is accomplished by writing with the beam at a different wavelength.

optical microphone—Laser-powered telephone device for analog communications that employs a vibrating plastic membrane as a transmitter to modulate laser light piped via optical fibers from a central exchange, omitting the need for transducers or modulators.

optical mode—In a crystal lattice, a mode of vibration that produces an oscillating dipole.

optical mosaic—1. Grouping of fibers to form a cross-section area that will make a light pattern for acceptance by a detector or other receiving element. 2. A construction in which fibers are grouped and regrouped to build up an area, usually with some degree or type of imperfection developing at the boundaries of the subgroup. When this boundary condition becomes very noticeable, it is called whiten wire.

optical pattern—Also called Christmas-tree pattern. In mechanical recording, the pattern observed when the surface of the record is illuminated by a light beam of essentially parallel rays.

optical port—An opening through which optical energy can pass.

optical pumping—The process of changing the number of atoms or atomic system in a set of energy levels as a result of the absorption of light incident on the material. This process causes the atoms to be raised from certain lower to certain higher energy levels, and it may cause a population inversion between certain intermediate levels.

optical pyrometer—A temperature-measuring device comprising a comparison source of illumination, together with some convenient arrangement for matching this source—either in brightness or in color—against the source whose temperature is to be measured. The comparison is usually made by the eye.

optical receiver—An electro-optical module that converts an optical input signal to an electrical output signal.

optical repeater—A device in a fiber optics system that amplifies the optical signal to overcome previous attenuation.

optical scanner—A computer-system input device that reads a line of printed characters and produces a corresponding electronic signal for each character.

optical scanning—A technique for machine recognition of characters by their images. Compare optical character recognition.

optical sound—A system of recording and reproducing sound by using modulated light areas at the side of motion-picture film.

Optical sound recorder.

optical spectrometer—An instrument with an entrance slit, a dispersing device, and one or more exit slits, with which measurements are made at selected wavelengths within the spectral range, or by scanning over the range. The quantity detected is a function of radiant power.

optical storage—In data processing, the storage of information on photographic film in a manner that allows it to be retrieved in a nondestructive fashion, usually with a photosensing device.

optical transmitter—An electro-optical module that converts an electrical input signal to an optical output signal.

optical twinning—A defect occurring in natural quartz crystals. The right quartz and left quartz both occur in the same crystal. This generally results in small regions of unusable material, which are discarded when the crystal is cut up.

optical video disc—Abbreviated OVD. A disc on the surface of which digital data is recorded at high packing densities in concentric circles or in a spiral using a laser beam to record spots, which are read by means of a reflected laser beam of intensity lower than the recording intensity. Up to 10^{11} bits can be recorded on a single disc, which is thus suitable for an hour of TV programming playback.

optical waveguide—1. A fiber used for optical communications. Analogous to a waveguide used for microwave communications. 2. An optical fiber with a high refractive index clad with a material having a lower index of refraction.

optic-electronic device—See optoelectronic device.

optics—That branch of physical science concerned with the nature and properties of the electromagnetic radiation known as light, including the infrared, visible, and ultraviolet regions.

optic scrambler—See fiber-optics scrambler.

optimization—1. The continual adjustment of a process for the best obtainable set of conditions. 2. Achieving the best possible solution to a problem in terms of a specified objective function.

optimize—To arrange instructions or data in computer storage in such a way that a minimum of machine time is required for access when instructions or data are called out.

optimum bunching—The bunching condition required for maximum output in a velocity-modulation tube.

optimum coupling—See critical coupling.

optimum damping—The value of damping that permits fast response with some overshoot; this value is about 65 percent of critical damping.

optimum frequency—The most effective frequency at a specified time for ionospheric propagation of radio waves between two specified points.

optimum load—The value of load impedance that will transfer maximum power from the source to the load.

optimum plate load—The ideal plate-load impedance for a given tube and set of operating conditions.

optimum reliability—The value of reliability that yields a minimum total successful mission cost.

optimum working frequency—The frequency at which transmission by ionospheric reflection can be expected to be most effectively maintained between two specified points and at a certain time of day. (For propagation by way of the F_2 layer, the optimum working frequency is often taken as being 15 percent below the monthly median value of the F_2 maximum usable frequency for a specified path and time of day.)

optocoupler—Sometimes referred to as optoisolator. 1. A light source (input) and a light detector (output) both housed in a single package, sealed against outside light. An electrical signal applied to the light source changes the amount of light emitted. The emitted light falls upon, and is collected by, the detector. These input electrical signals are thus coupled to the output. From the output, the signals perform normal electronic functions, such as driving amplifiers, triggering a thyristor power supply, or switching logic levels. 2. A device that transmits electrical signals, without electrical connection, between a light source (input) and a light detector (output). The input is generally an LED; the output could be a photodiode, phototransistor, a photodarlington, etc.

optoelectronic device—Also called opticelectronic device. 1. A device responsive to electromagnetic radiation in the visible, infrared, or ultraviolet spectral

regions of the frequency spectrum. It emits or modifies noncoherent or coherent electromagnetic radiation in these same regions, or utilizes such electromagnetic radiation for its internal operation. The wavelengths handled by these devices range from approximately 0.3 to 30 μm . Examples are LEDs, optical couplers, laser diodes, and photodetectors. 2. Electronic devices associated with light, serving as sources, conductors, or detectors. See also light.

optoelectronic integrated circuit—An integrated component that uses a combination of electroluminescence and photoconductivity in the performance of all or at least a major portion of its intended function.

optoelectronics—1. Technology dealing with the coupling of functional electronic blocks by light beams. 2. Circuitry in which solid-state emitters and detectors of light are involved. 3. A term that applies to devices or circuits in which light is emitted or detected by a solid-state technique. Through usage, however, the term implies a close tie with logic-level signals for driving emitters and coupling isolated circuits. The three leading technologies in the field are light-emitting diode (LED), liquid-crystal display (LCD), and neon gas discharge. LED technology spans a range of devices: both visible and infrared light-emitting lamps, optocouplers or optoisolators, and various visible light-emitting displays.

optoelectronic transistor—A transistor that has an electroluminescent emitter, a transparent base, and a photoelectric collector.

optographics—The use of techniques of drafted artwork, diamond ruling, high-resolution photoreproduction and vacuum deposition to generate and replicate precise patterns. In turn, these patterns make up such instruments as resolution targets, reticles, code discs, scales, and step wedges, which are generally applied to glass, and sometimes to film, plastic, quartz, or other substrates.

optoisolator—1. A coupling device consisting of a light sensor. Used for voltage and noise isolation between input and output while transferring the desired signal. 2. Any device that uses a light emitter and a photodetector to couple signals without any electrical connection. The use of the term is restricted by convention to devices employing an LED and semiconductor photodetector. 3. A small component that converts electrical signals to light signals, transmits the light signals across a short gap, and converts them back to electrical signals on the other side. Since no electrical connection exists across the gap, an optoisolator provides immunity to

Cutaway view.

Optoisolator.

electromagnetic interference and ground-loop problems. See also optocoupler.

optophone—A photoelectric device that converts light energy into sound energy. Thus, a blind person can “read” by ear by using a selenium cell and a circuit for converting the resulting signals into sounds of corresponding pitch.

orange peel—A term applied to the surface of a recording blank that resembles an orange peel. Such a surface has a high background noise.

orbit—1. The path of a body or particle under the influence of a gravitational or other force. For instance, the orbit of an celestial body is its path relative to another body around which it revolves. 2. To go around the earth or other body in an orbit.

orbital electron—An electron that is visualized as moving in an orbit around the nucleus of an atom or molecule, as opposed to a free electron.

orbital period—The time that it takes a satellite to complete one circumnavigation of its specific orbit.

OR circuit—See OR gate.

order—1. In computer terminology, the synonym for instruction, command, and—loosely—operation part. These three usages, however, are losing favor because of the ambiguity between them and the more common meanings in mathematics and business. 2. To place in sequence according to some rules or standards.

ordering—In a computer, the process of sorting and sequencing.

orders of logic—A measure of the speed with which a signal can propagate through a logic network (commonly referred to as orders-of-logic capability).

order tone—A tone sent over trunks to indicate that the trunk is ready to receive an order, and to the receiving operator that it is about to arrive.

OR device—A device whose output is logical 0 if, and only if, all the control signals are logical 0.

ordinary differential equations—Differential equations in which there is only one independent variable. The unknowns are functions of this variable, and all derivatives in the equations are with respect to this variable.

ordinary wave—Sometimes called the O-wave. One of the two components into which the magnetic field of the earth divides a radio wave in the ionosphere. The other component is called the extraordinary wave, or X-wave. When viewed below the ionosphere in the direction of propagation, the ordinary wave has counterclockwise or clockwise elliptical polarization, depending on whether the magnetic field of the earth has a positive or negative component, respectively, in the same direction.

ordinate—1. The vertical line, or one of the coordinates drawn parallel to it, on a graph. 2. The vertical scale on a graph. 3. A distance along the vertical or y-axis of a graph.

organ—In a computer subassembly, the portion that accomplishes some operation or function (e.g., arithmetic organ).

organic dye laser—A laser having a lasing material that is a fluorescing organic dye. It can produce, depending on the dye used, emission in any part of the visible spectrum into the near infrared and ultraviolet, and its most important property is continuous tunability over a broad spectrum.

OR gate—Also called an OR circuit. 1. A gate that performs the function of logical “inclusive OR.” It produces an output whenever any one (or more) of its inputs is energized. 2. A logic circuit that requires that at least one input be in the on state to drive the output into the on state. 3. A digital logic circuit that produces

a logical 1 output when any one or all of its outputs are logical 1. It produces a logical 0 output only when all of its inputs are logical 0.

Circuit.

TRUTH TABLE

INPUTS		OUTPUT
A	B	A + B
0	0	0
0	1	1
1	0	1
1	1	1

Truth table.

OR gate (using transistors).

orient—To position or otherwise adjust with respect to some reference point (e.g., to orient an antenna for best reception).

orientation—An adjustment of the time, relative to the start transition, that teletypewriter receiving apparatus starts selection.

oriented—In crystallography, a crystal in which the axes of its individual grains are aligned so that they have directional magnetic properties.

orifice—An opening or window—specifically, in a side or end wall of a waveguide or cavity resonator, an opening through which energy is transmitted.

origin—The point in a coordinate system where the axes meet.

original lacquer—An original disc recording made on a lacquer surface for the purpose of producing a master.

original master—Also called metal master or metal negative. In disc recording, the master produced by electroforming from the face of a wax or lacquer recording.

O-ring—A circular piece of material with a round cross section; it effects a seal under pressure.

ORION—An acronym for Oak Restricted Information and Operational Network.

orthicon—Also called an orthiconoscope. A camera tube in which a beam of low-velocity electrons scans a photoemissive mosaic capable of storing an electrical-charge pattern. It is more sensitive than the iconoscope.

orthiconoscope—See orthicon.

orthocode—An arrangement of black and white bars that resembles a piano keyboard and that can be read by an electric eye device.

orthocore—A completely closed flux memory device designed to almost duplicate the geometry of the ferrite core memory, eliminate the wiring of memory cores, and provide a plurality of wires through the memory element. The concept involves the formation of a group of plastic rods around a suitable wiring array.

orthogonal—A term that signifies that two signals (or signal attributes) are mutually transparent and noninterfering with each other. Frequency and amplitude modulation are orthogonal signal attributes.

orthogonal antennas—A pair of radar transmitting and receiving antennas, or a single antenna for transmitting and receiving, designed to permit detection of a difference in polarization between the transmitted and returned energy.

orthogonal axes—Axes that are perpendicular to each other. In an instrument, these axes usually coincide with its axes of symmetry.

OS/2—One of the first personal computer operating systems to support true multitasking with multiple address spaces and processes. Introduced by IBM in 1990.

OSCAR—Acronym for orbiting satellite carrying amateur radio. Acronym describing amateur satellites generally; with a number attached (e.g., AMSAT-OSCAR-16, or AO-16), the name of a specific ham radio satellite.

osciducer—A transducer in which information pertaining to the stimulus is provided in the form of deviation from the center frequency of an oscillator.

oscillate—To repeat a cycle of motions or to pass through a cycle of state with strict periodicity.

oscillating current—An alternating current; specifically, one that changes according to some law.

oscillating quantity—A quantity that alternately increases and decreases in value, but always remains within finite limits—e.g., the discharge of current from a capacitor through an inductive resistance (provided the inductance is greater than the capacitance times the resistance squared).

oscillating transducer—A transducer in which information pertaining to the stimulus is provided in the form of deviation from the center frequency of an oscillator.

oscillation—1. The state of a physical quantity when, in the time interval under consideration, the value of the quantity is continually changing in such a manner that it passes through maxima and minima (e.g., oscillating pendulum, oscillating electric current, and oscillating electromotive force). 2. Fluctuations in a system or circuit, especially those consisting of the flow of electric currents alternately in opposite directions; also, the corresponding changes in voltages. 3. *See* hunting, 1. 4. A periodic change in a variable, as in the amplitude of an alternating current.

oscillator—1. An electronic device that generates alternating-current power at a frequency determined by the values of certain constants in its circuits. An oscillator may be considered an amplifier with positive feedback, with circuit parameters that restrict the oscillations of the device to a single frequency. 2. Something that oscillates. In particular, a self-excited electronic circuit whose output voltage or current is a periodic function of time. 3. A generator of an alternating signal, continuous, sinusoidal, or pulsed.

oscillator circuit—*See* oscillator.

oscillator coil—A radio-frequency transformer that provides the feedback required for oscillation in the oscillator circuit of a superheterodyne receiver or in other oscillator circuits.

oscillator harmonic interference—Interference caused in a superheterodyne receiver by the interaction

of incoming signals with harmonics (usually the second harmonic) of the local oscillator.

oscillator-mixer-first-detector—A single stage that, in a superheterodyne receiver, combines the functions of the local oscillator and the mixer-first-detector.

oscillator padder—An adjustable capacitor placed in series with the oscillator tank circuit of a superheterodyne receiver. It is used to adjust the tracking between the oscillator and preselector at the low-frequency end of the tuning range.

oscillator radiation—The amount of voltage available across the antenna terminals of a receiver (or at a distance) traceable to any oscillators incorporated in the receiver.

oscillatory circuit—A circuit containing inductance and/or capacitance and resistance, so arranged or connected that a voltage impulse will produce a current that periodically reverses.

oscillatory current—A current that periodically reverses its direction.

oscillatory discharge—Alternating current of gradually decreasing amplitude which, under certain conditions, flows through a circuit containing inductance, capacitance, and resistance when a voltage is applied. *See also* damped waves.

oscillatory surge—A surge that includes both positive and negative polarity values.

oscillistor—A semiconductor bar that is subjected to a magnetic field and a direct current, and which generates oscillations believed to be due to diffusion of ions toward the surface of the semiconductor as a result of the magnetic field.

oscillogram—1. The recorded trace produced by an oscillograph. 2. A photograph of the luminous trace or image produced by an oscilloscope. 3. A record formed when the luminous trace or image produced by an oscilloscope is photographed.

oscillograph—1. An instrument primarily for producing a record of the instantaneous values of one or more rapidly varying electrical quantities as a function of time, or of another electrical or mechanical quantity. 2. An instrument used to record rapidly varying currents or voltages. May consist of a CRT oscilloscope with a camera attachment, or a mirror galvanometer with a lamp and optical system to trace rapid variations of electric current on a moving ribbon of photographic paper. The later type of oscillograph is often a multiple unit capable of recording 20 or more different current variations side by side on the same strip of paper.

oscillograph recorder—A form of mechanical oscillograph in which the waveform is traced on a moving strip of paper by a pen. It is used to record parameters that vary rapidly with time and can record variations in excess of 100 Hz. However, at these higher frequencies, the width of the trace is reduced. Typically such a device with a 40-mm trace width will record a signal up to 40 Hz at full trace width. If the maximum excursion of the recording pen is limited to 8 mm, it will record signals up to 100 Hz faithfully. Above 100 Hz, the signal width will be reduced. These recorders are available in multipen models to record several parameters on a single recorder.

oscillograph tube—*See* oscilloscope tube.

oscillography—The art and practice of utilizing the oscillograph.

oscillometer—An instrument for measuring oscillations (periodic variations) of any kind.

oscilloscope—1. An instrument in which the horizontal and vertical deflection of the electron beam of a cathode-ray tube are, respectively, proportional to a pair of applied voltages. In the most usual application

Oscilloscope.

of the instrument, the vertical deflection is a signal voltage and the horizontal deflection is a linear time base. 2. A cathode-ray tube with attendant amplifiers and control circuits for measuring and studying the waveforms of small currents and voltages. A CRT oscilloscope is particularly convenient for studying repetitive phenomena, but a tube with a long-delay phosphor can be used to analyze a single electrical pulse. An oscilloscope equipped with a camera (often of the instant type) becomes an oscillograph. 3. An electronic window that displays variations of voltage at any point in a circuit by displaying in graphic form on its screen the actual waveform of voltage plotted against time. In addition, an oscilloscope serves as an accurate ac/dc voltmeter and time-period counter. The typical scope is made up of five major interrelated parts: vertical amplifier section, horizontal amplifier section, sweep and synchronization circuits, picture tube (cathode-ray tube or CRT), and power supply. The electron beam strikes the fluorescent screen of the cathode-ray tube and temporarily produces a visible pattern or waveform of some fluctuating electrical quantity such as voltage. The pattern is employed to reveal the detailed variations in rapidly changing electric currents, potentials, or pulses.

oscilloscope differential amplifier—A device that amplifies and displays the voltage difference that exists at every instant between signals applied to its two inputs.

oscilloscope tube—Also called oscillograph tube. A cathode-ray tube that produces a visible pattern that is the graphical representation of electric signals. The pattern is seen as a spot or spots, which change position in accordance with the signals.

OSHA—Acronym for Occupational Safety and Health Act. A federal law that specifies the requirements an employer must follow in order to guard against employee illness and injury.

OSI—Abbreviation for Open Systems Interconnection. A layered architecture designed to permit interconnection between heterogeneous computer systems. Also, the international protocol for communications in a multiple-vendor environment.

OSO—Abbreviation for Orbiting Solar Observatory.

O-type backward-wave oscillator—A wide-band, voltage-tunable microwave oscillator that uses a fundamental or space harmonic with phase and group velocity of different signs.

outage—1. Loss of signal in a channel, usually the result of a dropout or a hit. 2. Status of equipment when it is out of service. Outages are termed *forced* when due to undesired occurrences, and *planned* when prescheduled, as for routine maintenance.

outconnector—In a flowchart, a connector indicating a point at which a flowline is broken to be continued at another point.

outdoor antenna—A receiving antenna located on an elevated site outside a building.

outdoor transformer—A transformer of weather-proof construction.

outer marker—In an instrument landing system, a marker located on a localizer course line at a recommended distance (normally about 4½ miles or 7.2 km) from the approach end of the runway.

outgas—The release of gas from a material over a period.

outgassing—1. A phenomenon in which a substance in a vacuum spontaneously releases absorbed and occluded constituents as vapors or gases. 2. De-aeration or other gaseous emission from a printed board assembly (printed board, component, or connector) when exposed to a reduced pressure or heat, or both.

outlet—1. The point where current is taken from a wiring system. 2. Convenience receptacle used for supplying power in the home, shop, or laboratory from power-company mains. 3. A point on the wiring system that can be tapped to provide electrical current for appliances or lights.

outlet box—Metal box that houses a switch or receptacle.

outline drawing—A drawing showing approximately overall shape, but no detail.

out of phase—1. Two or more waveforms that have the same shape, but do not pass through corresponding values at the same instant. 2. Relationship between periodic waves of the same frequency, but which do not pass through their maximum and minimum (or other corresponding) values at the same instant.

out-of-service jack—A jack, associated with a test jack, into which a shorted plug may be inserted to remove a circuit from service.

outphaser—In electronic organs, a circuit that changes a sawtooth wave to something approaching a square wave by adding to the sawtooth a second sawtooth of twice the frequency and half the amplitude in reverse phase, thus canceling the even harmonics.

outphasing—In electronic organs, a term applied to a method sometimes used for producing certain voices. Special circuitry, placed between the keying-system output and the formant filters, either adds or subtracts harmonics or subharmonics of the tone-generator signal.

output—1. The current, voltage, power, or driving force delivered by a circuit or device. 2. The terminals or other places where the circuit or device may deliver the current, voltage, power, or driving force. 3. Information transferred from the internal to the secondary or external storage of a computer. 4. The electrical quantity produced by a transducer, which is a function of the measurand. 5. The useful energy delivered by a circuit or device. 6. In logic circuits, frequently used to mean a change in condition between conducting and nonconducting. (It is like calling the coil of a relay the input and the contacts the output.) 7. The signal level at the output of an amplifier or other device. 8. A port or set of terminals at which a system or component delivers useful energy or a useful signal. Also the energy or signal delivered. The useful signal delivered by a recorder using a particular type of tape, usually at an arbitrarily fixed level of harmonic distortion (1 or 3 percent) and relative to the performance of a tape with standard characteristics. 9. The transfer of information from an information process. 10. The act of providing information from a device to the outside world. Generally accompanied by a device that inputs the information being output by the first device.

output amplifier—A circuit that energizes high-power-level devices upon application of a low-power-level input signal.

output axis—The axis around which the spinning wheel of a gyroscope precesses after the wheel has received an input.

output block—1. In a computer, a portion of the internal storage reserved for holding data that is to be transferred out. 2. A block of computer words treated as a unit and intended to be transferred from internal storage to an external location. 3. A block used as an output buffer.

output capability—The intensity of the strongest signal that a device can put out without exceeding certain limits of overload distortion.

output capacitance—1. Of an n -terminal electron tube, the short-circuit transfer capacitance between the output terminal and all other terminals, except the input terminal, connected together. 2. The shunt capacitance at the output terminal of a device.

output capacitive loading—The maximum capacitance that can be placed on the output of an operational amplifier at unity gain without increasing the phase shift to the point of inducing oscillation. The limiting value increases in direct proportion to the closed-loop gain.

output capacity—The number of loads that can be driven by the output of a circuit.

output device—1. The part of a machine that translates the electrical impulses representing data processed by the machine into permanent results such as printed forms, punched cards, and magnetic writing on tape. 2. Any device, such as a solenoid, motor starter, etc., that receives data from a programmable controller. 3. The unit of a computer, such as a card punch, that converts electrical signals into the form used by the output device, such as holes punched into cards.

output equipment—Equipment that provides information in visible, audible, or printed form from a computer.

output gap—An interaction gap with which usable power can be extracted from an electron stream.

output impedance—Also called dynamic output impedance. 1. The impedance measured at the output terminals of a transducer with the load disconnected and all impressed driving forces (including those connected to the input) taken as zero. 2. The impedance presented by a power supply to the load. It is calculated from the ratio of the change in output voltage (at the prescribed terminals) to the change in load current causing the change. The impedance is specified from dc to a stated maximum ac. 3. The impedance a device presents to its load.

output indicator—A meter or other device that indicates variations in the signal strength at the output circuits.

output limit—The maximum output signal available when an operational amplifier is operated in the saturation region.

output load current—The maximum current that the amplifier will deliver to, or accept from, a load. This rating includes the amount, however small, that is caused to flow in the feedback loop.

output meter—An alternating-current voltmeter that measures the signal strength at the output of a receiver or amplifier.

output-meter adapter—A device that can be slipped over the plate prong of the output tube of a radio receiver to provide a conventional terminal to which an output meter can be connected during alignment.

output offset voltage—1. The difference between the dc voltages at the two output terminals (or at the output terminal and ground in an amplifier that has one output) when both input terminals are grounded. 2. The output voltage of a negative-feedback op-amp circuit when the input voltage to the circuit is zero. An ideal op amp has zero output offset voltage.

output port—In a fluidic device, the port at which the output signal appears.

output power—1. The power that a system or component delivers to its load. 2. The maximum amount of power, limited by clipping or a specified value of distortion, that an amplifier is capable of delivering to a load of given value.

output resistance—The small-signal ac resistance of an operational amplifier seen looking into the output with no feedback applied and the output dc voltage near zero.

output saturation voltage—The lowest voltage level to which the collector of the output transistor can be reduced without degrading circuit performance.

output stage—The final stage in any electronic equipment. In a radio receiver, it feeds the speaker directly or through an output transformer. In an audio-frequency amplifier, it feeds one or more speakers, the cutting or recording head of a sound recorder, a transmission line, or any other load. In a transmitter, it feeds the antenna.

output transformer—A transformer used to couple the output stage of an amplifier to a load.

output tube—A power-amplifier tube designed for use in an output stage.

output unit—1. A computer unit that transfers data from the computer to an external device or from internal storage to external storage. 2. A device capable of recording data coming from the internal storage unit of a computer, e.g., card punch, line printer, CRT display, magnetic disk, or teletypewriter.

output voltage—The maximum output voltage that an amplifier will develop in the linear operating region (i.e., before the onset of saturation).

output voltage swing—The peak output voltage swing of an operational amplifier referred to zero that can be obtained without clipping.

output winding—The winding of a saturatable reactor, other than a feedback winding, through which power is delivered to the load.

outside lead—See *finish lead*.

outward WATS—Outward wide-area telephone service that permits a customer, for a monthly charge, to place outgoing station-to-station paid calls to telephones within prescribed service areas.

oven—An enclosure and associated sensors and heaters for maintaining components at a controlled temperature.

overall bandwidth—The width of a receiver resonance curve which represents the ratio of signal strength required at various frequencies of resonance to the signal strength at resonance in order to give constant output.

overall electrical efficiency (induction- and dielectric-heating usage)—Ratio of the power absorbed by the load material to the total power drawn from the supply lines.

overall loudness level—A measure of the response of human hearing to the strength of a sound. It is scaled in phons and is an overall single evaluation calculated for the levels of sound pressure of several individual bands.

overall thermoelectric generator efficiency—The ratio of electrical power output to thermal power input to the thermoelectric generator.

overall ultrasonic system efficiency—The acoustical power output at the point of application, divided by the electrical power input into the generator.

overbiasing—A setup procedure whereby the bias current of a tape recorder is adjusted to slightly beyond the point that produces maximum or peak output from the tape. Overbiasing reduces differences due to imperfect uniformity from one tape to another, at the cost of some high-frequency response.

overbunching — The condition in which the buncher voltage of a velocity-modulation tube is higher than required for optimum bunching of the electrons.

overcharging — Continued charging of a battery after it has reached a charged condition. This action damages the battery and shortens its life.

overcoat — A thin film of insulating material, either plastic or inorganic (e.g., glass or silicon nitride), applied over integral circuit elements for the purposes of mechanical protection and prevention of contamination.

overcompounding — In a compound-wound generator, use of sufficient series turns to raise the voltage as the load increases, in order to compensate for the increased line drop. In a motor, overcompounding makes it run faster as the load increases.

overcoupled circuit — A tuned circuit in which the coupling is greater than the critical coupling. The result is a broadband response characteristic.

Overcoupled circuit.

overcurrent — In a circuit, the current that will cause an excessive or even dangerous rise in temperature in the conductor or its insulation.

overcurrent protection — See overload protection.

overcurrent protective device — 1. A device operative on excessive current that causes and maintains the interruption of power in the circuit. 2. A device designed to open an electric circuit automatically at a predetermined overcurrent level.

overcurrent relay — A protective device that separates one portion of an electric network from another when current exceeds a predetermined value.

overcutting — In disc recording, the cutting through of one groove into an adjacent one when the level becomes excessive.

overdamping — Any periodic damping greater than the amount required for critical damping. See also aperiodic damping.

overdriven amplifier — An amplifier stage designed to distort the input-signal waveform by permitting the driving signal to drive it beyond cutoff or even into saturation.

overflow — 1. The condition occurring whenever the result of an arithmetic operation exceeds the capacity of the number representation in a digital computer. 2. The carry digit arising from (1) above. 3. The generation of a quantity that exceeds the capacity of the computer storage facility. 4. That portion of the result of an operation that exceeds the capacity of the intended unit of storage. 5. In a calculator, when a number that is entered, or the answer to a calculation, exceeds the capacity of the working register, the excess digits overflow the register. In most machines, an overflow signal (either audible or visible) indicates when overflow occurs.

overflow indicator — 1. A bistable trigger that changes state on the occurrence of overflow in the computer register with which it is associated. The overflow

indicator may be interrogated and/or restored to the original state. 2. In a calculator, a warning light or illuminated letter E to indicate existence of overflow condition.

overflow position — In a computer, an extra register position in which the overflow digit is developed.

overflow storage — Additional storage provided in a store and forward switching center of a computer to prevent the loss of messages (or parts of messages) offered to a completely filled line store.

overglaze — 1. A glass coating that is over another component or element, normally for physical or electrical protection purposes. 2. A glass compound in low-melting, vitreous form, used as a coating for passivate thick-film resistors and offering mechanical protection.

overglazed — Coated with a layer of printed and fired glass paste. Overglazing may be a solder barrier, a protective coating for resistors, or an insulator to prevent possible short circuits, as in the case of a wire bond crossing over a printed conductor.

overhang — 1. In terms of printed wiring, the inverted shelf of plating formed when conductor material is selectively removed from under the plating. The measurement between the base copper and the plating (generally refers to one side of the conductor only; thus, for a conductor width reduction, one must take two times the overhang). 2. The critical dimension by which the stylus overreaches the center spindle of a turntable when an offset tonearm is mounted for minimum tracking error.

overhead line — A conductor carried on elevated poles (e.g., telephone or telegraph wires).

overinsulation — In a coil, the insulating material placed over a wire that is brought from the center over the top or bottom wall.

overlap — 1. The amount by which the effective height of a scanning facsimile spot exceeds the nominal width of the scanning line. When the spot is rectangular, overlap may be expressed as a percentage of the nominal width of the scanning line. 2. To perform one operation at the same time that another operation is being performed; for example, to carry on input/output operations at the same time that instructions are being executed by the central processing unit. 3. The contact area between a film resistor and film conductor. 4. A mode of computer operation in which several processes take place seemingly simultaneously. In a multiprocessor system, simultaneous operation is truly possible. In a single-processor system, processes time-share the processor and appear to happen simultaneously but actually they occur in a time-sequential mode. Real time savings can be realized in either case, especially when extensive I/O to many devices of differing speeds is taking place.

overlapping contacts — Combinations of two sets of contacts actuated by a common means, each set closing in one of two positions and so arranged that the contacts of one set open after the contacts of the other set have been closed.

overlap radar — Long-range radar that is located in one sector but also covers a portion of another sector.

overlay — 1. In a computer, the technique of using the same blocks of internal storage for different routines during different stages of a problem, c.g., when one routine is no longer needed in internal storage, another routine can be placed in that storage location. 2. Memory management technique in which various routines occupy overlapping memory areas in succession. 3. A technique used to execute programs that are larger than the available memory size in systems without paging or segmentation capabilities. To utilize this method a program must be manually divided into a number of mutually exclusive groups of software modules.

overlying—The technique of repeatedly using the same blocks of internal storage during different stages of a program, e.g., when one routine is no longer needed, another routine can replace all or part of it.

overlay load module—A computer load module that has been divided into overlay segments and has been provided by the linkage editor with information that permits the desired loading of segments to be implemented by the overlay supervisor when requested.

overlay supervisor—A routine for control of the sequencing and positioning of computer program segments in limited storage during their execution.

overlay transistor—A transistor containing a large number of emitters connected in parallel to provide maximum power amplification at extremely high frequencies.

overlay zone—An area of memory used to contain different programs or data at different times during the operation of a system.

overline—In teletypewriter operation, the printing of one group of characters over another.

overload—1. A load greater than that which an amplifier, other component, or a whole system is designed to handle. It is characterized by waveform distortion or overheating. 2. An electrically operated counter that indicates the number of times all trunks are busy between the various telephone office units. 3. In an analog computer, a condition within a computing element or at its output that causes a significant computing error as a result of the saturation of one or more parts of the computing element. 4. The amount beyond the specified maximum magnitude of the measurand which, when applied to a transducer, does not cause a change in performance beyond specified tolerance. 5. Any input that causes a meter to read beyond its rated range (full-scale range for analog meters or "full" range for digital meters).

overload capacity—The level of current, voltage, or power beyond which a device will be ruined. It is usually higher than the rated load capacity.

overload level—The level at which a system, component, etc., ceases to operate satisfactorily and produces signal distortion, overheating, damage, etc.

overload margin—In an amplifier, the safety margin prior to the onset of overload to avoid clipping on transients. This also enhances the reproduction, giving it a smoother quality in many cases.

overload operating time—The length of time a system, component, etc., may be safely subjected to a specified overload current.

overload protection—Also called overcurrent protection. 1. A device that automatically disconnects the circuit whenever the current or voltage becomes excessive. 2. Effect of a device operative on excessive current, but not necessarily on short circuit, to cause and maintain the interruption of current flow to the device governed. 3. A device or circuit that protects a power supply from damage due to excessive current demand by the load. Some schemes are also designed to protect the load. See feedback current limiting.

overload recovery time—The time required for an amplifier to regain its ability to amplify within stated specification limits after distortion of the output voltage amplitude by the application of a specified input voltage exceeding the rated amplitude.

overload relay—A relay designed to operate when its coil current rises above a predetermined value.

overmodulation—Modulation greater than 100 percent. Distortion occurs because the carrier is reduced to zero during certain portions of the modulating signal.

Overmodulation.

overpotential—Also called overvoltage. A voltage greater than the normal operating voltage of a device or circuit.

overpressure—Pressure greater than the full-scale rating of a pressure transducer.

overpunch—Also called zone punch. A hole punched in one of the three top rows of a punch card and which, in combination with a second hole in one of the nine lower rows, identifies an alphabetic or special character.

overrange—The situation in which the signal being measured exceeds the full-scale value of a digital panel meter. Digital panel meters are designed to indicate this condition with a blinking display or the actuation of an appropriate symbol.

overranging—A feature of a digital panel meter or digital voltmeter wherein some indication is given (usually by blinking or flashing display) that the quantity being measured is too high in value for the range selected.

override—To manually or otherwise deliberately overrule an automatic control system or circuit and thereby render it ineffective.

oversampling—A technology used in CD players for noise reduction after digital-to-analog conversion. The higher the rate, the lower the noise. An oversampling rate of 256x virtually eliminates any noise, even at low recording levels.

overscan—A video-display effect in which the image is enlarged, resulting in its edges being off the screen.

overscanning—In a cathode-ray tube, the deflection of the electron beam beyond the normal limits of the screen. This is the deflection of the beam of the tube over an angle that surpasses the angle that subtends the suitable area of the screen.

overscan recovery—A characteristic of differential comparators that states the time required for the amplifier to recover to within some amount of voltage after a return to the screen of a CRT.

overshoot—1. The initial transient response, which exceeds the steady-state response, to a unidirectional change in input. 2. Amplitude of the first maximum excursion of a pulse beyond the 100-percent amplitude level expressed as a percentage of this 100-percent amplitude. 3. A transient rise beyond regulated output limits, occurring when the ac power input is turned on or off, and for line or load step changes. 4. The amount that the indicator travels beyond its final steady deflection when a new constant value of the measured quantity is suddenly applied to the instrument. The overtravel and deflection are determined in angular measure, and the overshoot is expressed as a percentage of the change in

steady deflection. 5. Reception of microwave signals at an unintended location because of an unusual atmospheric condition that sets up variations in the index of refraction. 6. Distance a motor shaft of a stepper motor can rotate beyond the step angle before it comes to rest at step-angle position.

Overshoot, 3.

overshoot distortion—See overthrow distortion.

overtemperature protection—A thermal relay or other protective device that turns off the power automatically in the event of the occurrence of an overtemperature condition.

over-the-horizon radar—A type of high-powered radar used to “see” over the horizon by means of scatter propagation.

over-the-horizon transmission—See scatter propagation.

overthrow distortion—Also called overshoot distortion. The distortion that occurs in a signal wave when the maximum amplitude of the signal wavefront exceeds the steady-state amplitude.

overtone—1. A component of a complex tone having a pitch higher than that of the fundamental component. The term *overtone* has frequently been used in place of *harmonic*, the n th harmonic being called the $(n - 1)$ st overtone. There is, however, ambiguity sometimes in the numbering of components of a complex sound when the word *overtone* is employed. Moreover, the word *tone* has many different meanings, so that it is preferable to employ terms that do not involve *tone* whenever possible. 2. A tone that is a harmonic of a fundamental tone.

overtone crystal—A quartz crystal cut so that it will operate at a harmonic of its fundamental frequency or at two frequencies simultaneously, as in a synthesizer.

overtravel—Distance in inches or degrees between the electrical operating position and the extreme position to which a switch actuator may be moved without switch damage.

overvoltage—1. The amount by which the applied voltage in a radiation-counter tube exceeds the Geiger-Mueller threshold. 2. See overpotential.

overvoltage protection—Also called transient suppression. The built-in capability of an electrical circuit to dissipate or shunt electrical impulse energy at a voltage low enough to ensure the survival of circuit components.

overvoltage protector—A device or circuit that protects the load by automatically shutting down a supply

when its output voltage exceeds a preset level. A crowbar is one form of overvoltage protection.

overvoltage relay—A relay designated to operate when its coil voltage rises above a predetermined value.

Ovshinsky effect—The characteristic of a special thin-film solid-state switch that has identical response to both positive and negative polarities so that current can be made to have the same magnitude in both directions.

O-wave—See ordinary wave.

Owen bridge—A four-arm alternating-current bridge for measuring self-inductance in terms of capacitance and resistance. One arm, adjacent to the unknown inductor, comprises a capacitor and resistor in series. The arm opposite the unknown consists of a second capacitor, and the fourth arm is a resistor. Usually the bridge is balanced by adjusting the resistor in series with the first capacitor, and also the resistor in series with the inductor. The balance is independent of frequency.

$$C_3 R_4 = C_1 R_2 \\ L = C_1 R_2 R_3$$

Owen bridge.

oxalizing—See surface insulation.

oxidation—1. Commonly known as rust when ferrous material is involved. The increase in oxygen or in an acid-forming element or radical in a compound. 2. The process of combining with oxygen. More generally, the process by which atoms lose valence electrons or begin to share them with more electronegative atoms. 3. The reaction of oxygen on a compound. Usually detected by a change in the appearance or feel of the surface or by a change in physical properties or both.

oxide—In magnetic recording, microscopic particles of ferric oxide dispersed in a liquid binder and coated on a recording-tape backing. These oxides are magnetically hard—i.e., once magnetized, they remain so permanently unless exposed to a strong magnetic field.

oxide breakdown voltage—That voltage which exceeds gate oxide dielectric breakdown, causing a gate-to-substrate short.

oxide-coated cathode—Also called Wehnelt cathode. A cathode that has been coated with oxides of alkaline earth metals to improve its electron emission at moderate temperatures.

oxide isolation—Electrical isolation of a circuit element by a layer of silicon oxide formed between the element and the substrate.

oximeter—An instrument for measuring the oxygenation of the blood, usually by measuring light transmission through the ear lobe. It uses a photoelectric cell and a source of illumination.

ozone—An extremely reactive form of oxygen, normally occurring around electrical discharges and present

in the atmosphere in small but active quantities. It is faintly blue and has the odor of weak chlorine. In sufficient concentrations, it can break down certain rubber insulations under tension (such as a bent cable).

ozone — ozone-producing radiation

ozone-producing radiation—Ultraviolet energy shorter than about 220 nanometers, which decomposes oxygen (O_2), thereby producing ozone (O_3). Some ultraviolet sources generate energy at 184.9 nanometers, which is particularly effective in producing ozone.

P

p—1. Abbreviation for power (combining form, as in pf for power factor), or plate of an electron tube. 2. Letter symbol for the prefix pico- (10^{-12}).

P—Symbol for permeance.

pA—Letter symbol for picoampere.

PABX or pabx—Abbreviation for private automatic branch exchange. 1. A small, local, user-owned automatic telephone exchange serving extensions in a business complex that accommodates the transmission of calls to and from the public telephone network. 2. A private branch exchange in which connections are made by remote-controlled switches.

pacemaker—Also called pacer or electronic pacemaker. An electronic instrument for starting and/or maintaining the heartbeat. The instrument is essentially a pulse generator with its output applied either externally to the chest or internally to the heart muscle. In cases requiring long-term application, the device is surgically implanted in the body, and its electrodes contact the heart directly.

pacer—See pacemaker.

pack—1. In computer programming, to combine several fields of information into one machine word. 2. To compress data in a storage medium by taking advantage of known characteristics of the data in such a way that the original data can be recovered; e.g., to compress data in a storage medium by making use of bit or byte locations that would otherwise go unused.

package count—The number of packaged circuits in a system or subsystem.

packaged magnetron—An integral structure comprising a magnetron, its magnetic circuit, and its output matching device.

package lid—A flat cover plate that is used to seal a package cavity.

packaging—The physical process of locating, connecting, and protecting devices, components, etc.

packaging density—1. The number of devices or equivalent devices per unit volume in a working system or subsystem. 2. In a computer, the number of units of information per dimensional unit. 3. Quantity of functions (components, interconnection devices, mechanical devices) per unit volume, usually expressed in qualitative terms, such as high, medium, or low.

packed data—Information that has been compressed to make optimal use of memory. Four BCD digits can be packed into a 16-bit memory location.

packed decimal—Numerical representation in which two or more BCD digits are present in every word.

packet—1. A group of binary digits, including data and call control signals, that is switched as a composite whole. The data call-control signals, possible error-control signals, and possible error-control information are arranged in a specific format. 2. A group of ASCII characters (information) surrounded by control signals and

error-detection features. The control signals help recognize the presence of a packet and tell any intervening switching equipment where the packet should be sent. 3. A digital communications technique involving the transmission of a short burst of data in a protocol format that contains addressing, control, and error-checking information, along with the field information, in each transmission burst. Packet can also refer to the fixed-length data unit sent over a communications network. A packet contains data plus the addresses of the sending and receiving terminals, control information, and error-checking information. 4. A unit of data to be routed from a source node to a destination node. 5. Common short form of "packet radio."

packet assembler/disassembler—See PAD.

packet-mode terminal—Data-terminal equipment that can control and format packets and transmit and receive them.

packet radio—1. The time-division multiplexing of a radio channel so large numbers of users can share one channel without interfering with one another. Users don't know that they are sharing the channel with anyone else. The name *packet* is derived from the fact that each message is sent in a package. It has three parts: the address and return address, called the header; the data or message part; and the trailer, which is an error-detection scheme. 2. A method of communication that encodes information digitally and in such a manner as to virtually ensure error-free copy at the receiving station. A packet consists of binary data (which might be ASCII, Baudot, or some other code), and the modulation techniques may be essentially the same as for conventional ASCII or rtty, although the exact interpretation of the tones may be different. In a packet the individual characters or bytes are run together with no space at all between. This eliminates the need for both the start and stop bits as well as the dead time between characters. The analogs of start and stop bits are sent only for the beginning and end of the packet, and the transmitter is keyed only while information is actually being sent. 3. The most popular form of amateur radio digital communications, in which computers hooked to radios exchange data in packets.

packets—Data that is transmitted through networks and broken up into small packets (localized in time) rather than being sent as a continuous byte stream. This allows multiple transmissions to share the same line and also facilitates error detection.

packet-switched network—A data-communications network that transmits packets. Packets from different sources are interleaved and sent to their destination over virtual circuits. The term includes PDNs and cable-based LANs.

packet switching—1. An efficient way to prevent transmission capacity consumption during the silent periods in voice conversation by compressing the conversations of a number of speakers onto a smaller number

of channels. In one such system, channel capacity is allocated only when appropriate hardware detects that a subscriber is actively speaking. 2. Transfer of data by means of addressed packets, whereby interim point-to-point channels are available only during the transmission of one packet. The channel then becomes available for the transfer of packets from the same or other messages. (Contrast with circuit switching, where the data network determines the end-to-end routing before the entire message transfer.) 3. The transmission of data by means of addressing packets, whereby a transmission channel is occupied for the duration of transmission of the packet only. The channel is then available for use by packets being transferred between different data-terminal equipment. 4. A method of digital communication in which messages are divided into packets of bit size determined by the needs of the transmission network, and are transferred to their destination in a store-and-forward manner over multiple virtual circuits, which are dedicated to the connection only for the duration of the packet's transmission. 5. A method of transmitting units of data (called packets) through a mesh network. There is no physical circuit established between end points; instead, each packet is individually relayed from one switching node to the next. Individual packets may take different routes through the switching network. 6. The use of software to route messages dynamically from source to destination within a communications network. 7. Data transmission method that divides messages into standard-sized packets for greater efficiency of routing and transport through a network.

packing—Excessive crowding of carbon particles in a carbon microphone. The abnormal pressure of the particles lowers their resistance. As a result, the current increases excessively and fuses some of the particles together, further lowering the resistance and raising the current. Packing causes the sensitivity of the microphone to decrease.

packing density—1. In a digital computer, the number of units of desired information contained within a storage or recording medium. 2. The amount of digital information recorded along the length of a tape measured in bits per inch (bpi).

packing factor—The number of pulses or bits of information that can be written on a given length of magnetic surface.

packing fraction—1. The fraction of total cross-sectional area composed of the fiber cores in a fiber-bundle assembly. 2. The ratio of the active core area of a fiber bundle to the total area at its light-emitting or receiving end.

pack unit—A term applied to a compact combination radio transmitter/receiver that can be carried or strapped on the back. Some pack units are popularly known as walkie-talkies.

PACSAT—Abbreviation for *packet satellite*. Satellite used to store and forward amateur digital (packet radio) messages.

pad—1. A transducer capable of reducing the amplitude of a wave without introducing appreciable distortion. 2. A device inserted into a circuit to introduce transmission loss or to match impedances. 3. A metal electrode that is connected to the output of a diathermy machine and placed on the body over the region being treated. 4. In integrated circuit technology, the bonding area. 5. Also called land. The portion of the conductive pattern on printed circuits designated for mounting or attachment of components. 6. A metallized area on the surface of an active substrate as an integral portion of the conductive interconnection pattern to which bonds or test probes may be applied. 7. A passive resistor network that reduces the

power level of a signal. A pad may be utilized to match unequal input and output impedances for proper interface.

Pads, 2.

PAD—Abbreviation for packet assembler/disassembler. Equipment providing packet assembly and disassembly facilities.

pad character—A character introduced to consume time while a function (usually mechanical, such as carriage return, form eject, etc.) is being accomplished.

padder—Also called padder capacitor or padding capacitor. A relatively high-capacitance trimmer capacitor in the oscillator circuit of a superheterodyne receiver that permits calibration of the low-frequency end of the tuning range so that it tracks with the tuning dial markings.

padder capacitor—*See* padder.

padding—A technique used in digital information systems whereby an information block that is only partially filled is completed by the insertion of dummy data.

padding capacitor—*See* padder.

page—1. A natural grouping of memory locations by higher-order address bits. In an 8-bit microprocessor, $2^8 = 256$ consecutive bytes often may constitute a page. The words on the same page only differ in the lower-order 8 address bits. 2. A full screen of information.

page printer—A high-speed unit that prints characters one at a time to full page format.

pager—Pocket-sized radio receiver that generates audible or physical signals when the user is paged.

page scrolling—The ability of the system to “flip” through the pages of a document, usually in both forward and backward directions, allowing access to all text of a multipage document.

pagination—The electronic makeup of complete page images, including all graphics, for automatic imaging onto photographic paper, negatives, or offset printing plates.

paging—1. Methods for locating and exchanging segments to and from the main computer memory. 2. To summon a particular person over a public address system, or by selectively calling him or her on a pocket radio receiver that emits an alerting signal. 3. In the case of a CRT, switching from one page of information to the next. 4. In the case of a memory, a logical block of storage used for memory management (for example, 1 K words). An address is then specified by a page address (number) and a displacement (address within the page).

paging receiver—Small, lightweight FM radio receiver carried by persons who need to be paged when they are away from their phones.

paging system—Communications system for summoning individuals (doctors, nurses, hospital personnel, etc.) or making public announcements.

paint—1. Vernacular for a target image on a radar-scope. 2. To draw vectors when the beam is unblanked. 3. To shade the interior of a closed graphical image with diagonal lines, cross hatch, points, etc.

pair—In electric transmission, two like conductors employed to form an electric circuit.

paired cable—1. A cable in which all of the conductors are arranged in the form of twisted pairs, none

of which is arranged with others to form quads. 2. Cable in which the conductors are combined in pairs. Two wires are twisted about each other, and each wire of the pair has a distinctive color of insulation.

pairing — 1. In television, the imperfect interlace of lines comprising the two fields of one frame of the picture. Instead of being equally spaced, the lines appear in groups of two—hence the name. 2. In television, an effect in which the lines of one field fail to fall exactly within the lines of the following field, both fields comprising one frame of the picture. The lines of the two fields fall directly over each other when the effect is more exaggerated, and the vertical definition is suitably decreased by half. 3. A faulty interlace scan in which the alternate scanning lines tend to overlap each other. The effect is a severe reduction in vertical resolution capability.

PAL — Abbreviation for phase alternating line. 1. Pertaining to a color television system in which the subcarrier derived from the color burst is inverted in phase from one line to the next in order to minimize hue errors that may occur in color transmission. 2. The German-developed TV color system used in Europe (except for France). It features 625 lines per frame and 50 fields per second. (Generally, this method gives higher-resolution TV pictures than the American NTSC 525-line color system.) PAL uses a similar transmission method as NTSC, but with the color information switched 180° on alternate scan lines. The subcarrier frequency is 4.43 MHz.

Palmer scan — A combination of circular and conical scans. The beam is swung around the horizon at the same time the conical scan is performed.

PALplus — An enhanced PAL transmission system used in Europe. It offers sharper images in wide screen format.

PAM — Abbreviation for pulse-amplitude modulation.

PAM/FM — Frequency modulation of a carrier by pulses that, in turn, are modulated by data.

PAM/FM/FM — Frequency modulation of a carrier by subcarriers modulated by pulses that, in turn, are modulated by data.

pan — 1. To move a television or movie camera slowly up and down or across a scene to secure a panoramic effect. 2. To move the camera up and down, or back and forth, in order to keep it trained on a moving object.

pan and tilt — An accessory upon which a camera is mounted to facilitate movement (panning and tilting) by the operator or by a remote control unit.

pancake coil — A coil shaped like a pancake, usually with the turns arranged in a flat spiral.

panel — 1. An electrical switchboard or instrument board. 2. A mounted plate of metal or insulation for the controls and/or other parts of equipment.

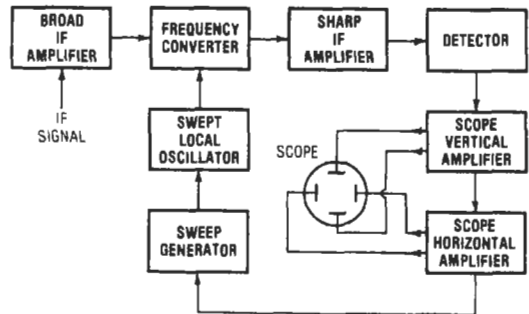

Panel meter.

panel code — Prearranged code designed for visual communications between ground units and friendly aircraft.

panel layout — The general physical layout of an electrical control panel with all relays, disconnect switch, control transformer, terminal strip, etc.

panning — See pan.

panoramic adapter — An attachment used with a search receiver to provide, on an oscilloscope screen, a visual presentation of the frequencies above and below the center frequency to which the search receiver is tuned.

Panoramic adapter.

panoramic display — A display that shows at the same time all the signals received at different frequencies.

panoramic presentation — A presentation of signals as intensity pips (vertical deflections) along a line. The horizontal distance along the line represents frequency.

panoramic radar — A non-scanning radar that transmits signals omnidirectionally over a wide beam.

panoramic receiver — A radio receiver that displays, on the screen of a cathode-ray tube, the presence and relative strength of all signals within a wide frequency range. Used in communications for monitoring a wide band, locating open channels quickly, indicating intermittent signals or interference, and monitoring a frequency-modulated transmitter.

panoramic sonic analyzer — A heterodyne-type instrument that separates the frequency components of a complex waveform and displays them on an oscillographic screen, indicating both frequency and magnitude.

pan-pot — A potentiometer used to adjust the stereo balance of a monophonic signal, allowing it to be positioned anywhere across the stereo range.

pan-range — Intensity-modulated A-type radar indication with slow vertical sweep applied to video. Stationary targets give solid vertical deflection, and moving targets give broken vertical deflection.

pantography — A system for transmitting and automatically recording radar data from an indicator to a remote point.

pantophonic system — See ambisonic reproduction.

paper capacitor — 1. A fixed capacitor consisting of two strips of metal foil separated by oiled or waxed paper or other insulating material, the whole rolled together into a compact roll. The foil strips can be staggered so that one strip projects from each end, or tabs can be added. The connecting wires are attached to the strips or tabs. 2. A capacitor with a dielectric consisting of paper, usually impregnated.

Paper capacitor.

paper electrophoresis—Analytical instrument for a technique in which ions migrate along a strip of porous filter paper saturated with an electrolyte when a potential gradient is applied across the length of the strip. It is used to identify ion types in analysis of serums, proteins, biochemicals, inorganic ions, rare earths, etc.

paper tape—1. A continuous strip of paper into which data is recorded as a series of holes along its length. Data is read by a paper-tape reader sensing the pattern of holes, which represent coded data. 2. One of the slowest but oldest and cheapest methods of storing archival information in a computer system. Data is stored in punched-hole sequences on a strip of tape.

paper-tape punch—A device that places binary characters on a paper tape in the form of holes punched in appropriate channels on the tape. A binary 1 is indicated by the presence of a hole, and a 0 is indicated by the absence of a hole.

paper-tape reader—1. A device that senses and translates holes punches in a tape into electrical signals. 2. A device that senses the presence or absence of holes in punched paper tape, one character at a time, and produces electrical signals suitable for computer input.

PAR—See precision approach radar.

parabola—Locus of points equidistant from a fixed point and a straight line.

parabola controls—Sometimes called vertical-amplitude controls. Three controls in a color television receiver employing the magnetic-convergence principle. They are used for adjusting the amplitude of the parabolic voltages applied, at the vertical-scanning frequency, to the coils of the magnetic-convergence assembly.

parabolic antenna—1. An antenna with a radiating element and a parabolic reflector that concentrates the radiated power into a beam. 2. A highly directional microwave antenna that uses a parabolic reflector. 3. The most frequently found satellite TV antenna, which takes

Parabolic antenna.

paper electrophoresis — parallel arithmetic unit

its name from the shape of the dish described mathematically as a parabola. The function of the parabolic shape is to focus the weak microwave signal hitting the surface of the dish (antenna) into a single focal point in front of the dish, where the feedhorn is usually located.

parabolic microphone—A microphone positioned at the focus of a parabolic sound reflector to give highly directional characteristics.

parabolic reflector—A metallic sheet formed so that its cross section is in the shape of a cylindrical parabola. The antenna elements are placed along the line that runs through the focal point of the parabola, parallel to the leading edge of the reflecting sheet.

parabolic-reflector microphone—A microphone employing a parabolic reflector for improved directivity and sensitivity.

parabolic/shotgun mike—A microphone with a reflector/director that concentrates sound energy so that specific sounds can be heard at a distance with minimum interference from other sound sources.

paraboloid—A reflecting surface of paraboloidal shape (the shape of a surface formed by rotating a parabola about its axis of symmetry).

paraboloidal reflector—A hollow concave reflector that is a portion of a paraboloid of revolution.

paradigm—In programming, an established coding model or structure.

paraffin—A vegetable wax having insulating properties.

paragraphic equalizer—A contraction of *parametric* and *graphic*. A graphic equalizer in which the center frequency of each band is adjustable. May also have adjustable Q .

parallax—1. An optical illusion that makes an object appear displaced when viewed from a different angle. Thus, a meter pointer will seem to be at different positions on the scale, depending from which angle it is read. To eliminate such errors, the eye should be directly above the meter pointer. 2. The apparent displacement of a meter pointer from its true position on the scale, when the observer's eye is not centered over the pointer.

parallel—Also called shunt. 1. Connected to the same pair of terminals, so that the current can branch out over two or more paths. 2. A method of connecting an electric circuit whereby each element is connected across the other. The addition of all the currents through each element equals the total current of the circuit. 3. In electronic computers, the simultaneous transmission of, storage of, or logical operations on a character or other subdivision of a word, using separate facilities for the various parts. 4. Indicating a type of computer in which several operations are performed on the same or different data at once. 5. A type of interface in which all bits of data in a given byte are transferred simultaneously, using a separate data line for each bit.

parallel access—Also called simultaneous access. The process of taking information from or placing information into computer storage whereby the time required for such access depends on simultaneously transferring all elements of a word from a given storage location.

parallel adder—A conventional technique for adding, in which two multibit numbers are presented and added simultaneously in parallel.

parallel addition—A form of addition in which the computer operates simultaneously on each set of corresponding digits of two numbers.

parallel arithmetic unit—In a computer, a unit in which separate equipment operates (usually simultaneously) on the digits in each column.

parallel buffer—An electronic device (for example, magnetic cores or flip-flops) used for temporary parallel storage of digital data.

parallel circuit—1. A circuit in which all positive terminals are connected to a common point, and all negative terminals are connected to a second common point. The voltage is the same across each element in the circuit. 2. A circuit in which the current has two or more paths to follow. Two electrical elements are in parallel if (and only if) both terminals of both elements are electrically connected.

parallel computer—A computer in which the digits or data lines are handled at the same time by separate units.

parallel connection—Also called shunt connection. Connection of two or more parts of a circuit to the same pair of terminals, so that current divides between the parts; as contrasted with a series connection, in which the parts are connected end to end so that the same current flows through all.

Parallel-connected resistors.

parallel cut—A Y-cut in a crystal.

parallel digital computer—A computer in which the digits are handled in parallel. Mixed serial and parallel machines are frequently called serial or parallel according to the way arithmetic processes are performed. For example, a parallel digital computer handles decimal digits in parallel, although the bits that comprise a digit might be handled either serially or in parallel.

parallel feed—Also called shunt feed. Application of a dc voltage to the plate or grid of a tube in parallel with an ac circuit, so that the dc and ac components flow in separate paths.

parallel gap solder—Passing a high current through a high-resistance gap between two electrodes to remelt solder, thereby forming an electrical connection.

parallel gap welding—1. A method of resistance welding in which both electrode tips are in close proximity to each other, being separated by a small gap or insulating material, approach the work from the same direction, and contact only one of the two materials being welded. 2. Type of resistance welding wherein electrodes contact the work from one side only. Mechanism by which bonding occurs is virtually always fusion. The

Parallel gap welding.

process is well suited to welding component leads to planar surfaces, such as IC leads to printed circuit conductors. 3. Passing a high current through a high-resistance gap between two electrodes that are applying force to two conductors, thereby heating the two work pieces to the welding temperature and effecting a welded connection.

paralleling reactor—A reactor for correcting the division of load between parallel-connected transformers with unequal impedance voltages.

parallel interface—1. A multilane channel that transfers 8 parallel bits. 2. A port that sends or receives the 8 bits in each byte all at one time. Many printers likely to be used in homes use a parallel interface to connect to the computer. 3. A link between two devices in which all the information transferred between them is transmitted simultaneously over separate conductors.

parallel light—See collimated light.

parallel load—See shift, 2.

parallelogram distortion—In camera or image tubes, a form of distortion that amounts to a skewing of the reproduced image laterally across the CRT face.

Parallelogram distortion.

parallel operation—Also called master/slave operation. 1. The connecting of two or more power supplies so that their outputs are tied together, permitting the accumulated current from all units to a common load. In regulated power supplies, interconnections other than the output terminals themselves may be required. For example, the amplifiers of all units but one may be made inoperable, and this single amplifier would control all regulating elements. 2. Pertaining to the manipulation of information within computer circuitry, in which the digits of a word are transmitted simultaneously on separate lines. Faster than serial operation, but requires more equipment. 3. Type of information transfer whereby all digits of a word are handled simultaneously.

parallel output—1. An output arrangement in which two or more bits, channels, or digits are available simultaneously. 2. Simultaneous availability of two or more bits, channels, or digits.

parallel-plate oscillator—A push-pull, ultrahigh-frequency oscillator circuit that uses two parallel plates as the main frequency-determining elements.

parallel-plate waveguide—A pair of parallel conducting planes for propagating uniform cylindrical waves that have their axes normal to the plane.

parallel port—1. Interface located on a host adapter card used to connect a disk drive or printer to the PC. 2. A port on a computer used to send several bits in parallel (usually 8 bits). Many printers connect to a parallel port. 3. A data communication channel that uses one wire for each bit in a single byte.

parallel processing—1. In a computer, the processing of more than one program at a time through more

than one active processor. 2. The simultaneous execution of two or more processes in multiple devices, such as channels or processing units.

parallel programming—A method of parallel operation of two or more power supplies in which the feedback terminals (voltage control terminals) of the units are also connected in parallel. Often, these terminals are connected to a separate programming source.

parallel recording—A technique in which the record heads in a head stack are energized simultaneously to record a specific set of bits.

parallel resonance—In a circuit comprising inductance and capacitance connected in parallel, the steady-state condition that exists when the current entering the circuit from the supply line is in phase with the voltage across the circuit.

parallel-resonant circuit—An inductor and capacitor connected in parallel to furnish a high impedance at the frequency to which the circuit is resonant.

Parallel-resonant circuit.

parallel-rod oscillator—An ultrahigh-frequency oscillator circuit in which the tank circuits are formed by parallel rods or wires.

parallel-rod tank circuit—A tank circuit consisting of two parallel rods connected at their far ends. This is done to provide the small values of inductance and capacitance in parallel required for ultrahigh-frequency circuits.

parallel-rod tuning—A tuning method sometimes used at ultrahigh frequencies. The transmitter, receiver, or oscillator is tuned by sliding a shorting bar back and forth on two parallel rods.

parallel search storage—A type of computer storage in which one or more parts of all storage locations are queried at the same time. *See also* associative storage.

parallel-series circuit—Also called shunt-series circuit. Two or more parallel circuits connected together in series.

parallel shift—*See* shift, 2.

parallel splice—A device in which two or more conductors are joined and lie parallel and adjacent to each other.

parallel storage—Computer storage in which characters, words, or digits are accessed simultaneously.

parallel-T network—Also called twin-T network. A network composed of separate T-networks (usually two), the terminals of which are connected in parallel.

parallel-T oscillator—An RC sine-wave oscillator that provides phase inversion at one discrete frequency and is so connected that positive feedback results only when phase inversion occurs.

parallel-tracking arm—Pickup system that allows phonograph cartridge to track on the true radius of the record, as the recording was made, thereby minimizing lateral tracking error.

parallel programming — parameter extraction

Parallel-T network.

parallel transfer—Data transfer in which all characters of a word are transferred simultaneously over a set of lines.

parallel transmission—1. In a computer, the system of information transmission in which the characters of a word are transmitted (usually simultaneously) over separate lines, as contrasted with serial transmission. 2. The simultaneous transmission of the bits making up a character, via either separate channels or different carrier frequencies on one channel. 3. The simultaneous transmission of a number of signal elements, either as tones or as dc pulses. 4. Transmission mode in which a number of bits of information are sent simultaneously (usually unidirectional) over separate lines (for example, eight bits over eight lines).

parallel-wire line—A transmission line consisting of two wires a fixed distance apart.

parallel-wire resonator—A resonator circuit consisting of two parallel wires connected at one end to the oscillator tube or transistor. The other end is short circuited and can be adjusted for the desired frequency.

Paraloc—A phase-shift amplifier whose positive feedback results in an oscillation that is frequency modulated by the change in a sensed variable. The sensor is one arm of a resistance bridge.

paramagnetic—1. Having a magnetic permeability greater than that of a vacuum but less than that of ferromagnetic materials. Unlike the latter, the permeability of paramagnetic material is independent of the magnetizing force. 2. Characteristic of a substance that is attracted by a magnetic field, but which has a permeability only slightly greater than 1.

paramagnetic amplifier—A parametric amplifying device in which a nonlinear element (varactor diode) is pumped at twice the frequency of the signal to be amplified. Amplification is obtained because the pumped state of the element can be returned to the normal state by an input signal of relatively low power, thus releasing the excess energy to an external circuit at the signal frequency.

paramagnetic material—A material having a permeability that is slightly greater than that of a vacuum and which is approximately independent of the magnetizing force, i.e., the material is broadly considered nonmagnetic.

paramagnetism—Magnetism that involves a permeability somewhat greater than unity.

parameter—1. A constant or element, the value of which characterizes the behavior of one or more variables associated with a given system. 2. A measured value that expresses performance. 3. A test variable used as an arbitrary constant. 4. A variable that is given a constant value for a specific purpose or process. 5. A measurable factor that indicates the degree of quality, performance, or capability of a device. 6. An element that determines the characteristics or behavior of the data communication equipment.

parameter extraction—A technique that reduces the bandwidth required to transmit a given data sample by means of an information-describing irreversible transformation. These transformations are considered irreversible in that, while they provide useful descriptions of the input

signal, they so distort the signal that it is impossible to reconstruct the original waveform.

parameter format—The structure and significance of information that must be assigned values before a generic package may be generated.

parameters—Those indicators of device performance that relate one aspect of its behavior with another. Hence, input resistance is a parameter relating input voltage with input current, and current gain is a parameter relating output current with input current.

parameter spread—The inevitable variation in value of the parameters of a given device type due to manufacturing tolerances. Often expressed in terms of the various statistical distributions.

parameter tags—Constants used by several programs.

parametric amplification—A means of amplifying optical waves whereby an intense coherent pump wave is made to interact with a nonlinear optical crystal to produce amplification at two other optical wavelengths.

parametric amplifier—1. A low-noise device for amplifying signals in the UHF and microwave regions of the electromagnetic spectrum. The essential element of the amplifier is a semiconductor crystal (varactor). By its very nature the diode contributes very little noise, unlike an amplifier utilizing electron tubes, where the random nature of the electron emission from the hot cathode produces large fluctuations in the current, called shot noise. Thus, the signals to be amplified can be of extremely low levels. 2. A microwave amplifier having a base element whose reactance can be varied periodically by an ac voltage at a pumping frequency. Operation is at room temperature. 3. An amplifier that uses a varying parameter, such as reactance, to take power from a local source of energy to amplify an input signal. (The local source of energy is usually a pump oscillator, operating at twice the frequency of the signal to be amplified.) 4. A low-noise amplifier that depends on a high-frequency source (Gunn-effect pump) rather than a dc source to amplify weak input signal. It works like a maser. The input signal modulates an electron beam, and the pump amplifies it while it travels to the output coupler.

parametric converter—An inverting or noninverting parametric device used to convert an input signal at one frequency into an output signal at a different frequency.

parametric device—A device whose operation depends essentially upon the time variation of a characteristic parameter usually understood to be a reactance.

parametric down-converter—A parametric converter in which the output signal is at a lower frequency than the input signal. An equalizer whose center frequency is continuously variable over a given frequency range, and whose Q (slope rate) is adjustable. If Q is nonadjustable, the equalizer is "quasi-parametric," "tunable," or "sweep-able."

parametric excitation—A term referring to the method of exciting and maintaining oscillation in either an electrical or mechanical dynamic system, in which excitation results from a periodic variation in an energy storage element in a system such as a capacitor, inductor, or spring constant.

parametric frequency converter—A frequency converter that utilizes the variation of the reactance parameter of an energy-storage element for frequency conversion.

parametric modulator—A modulator that utilizes the variation in the reactance parameter of an energy-storage element to produce modulation.

parametric oscillator—A device using a parametric amplifier inside a resonant optical cavity to generate a

frequency-tunable coherent beam of light from an intense laser beam of fixed frequency. It is tuned by varying the phase-matching properties of the nonlinear material.

parametric testing—Testing based on reasonably precise measurements of voltages or currents.

parametric tests—Tests that measure dc conditions of a chip, such as maximum current, leakage, and output drive.

parametric up-converter—A parametric converter in which the output signal is at a higher frequency than the input signal.

parametric value—The actual information that is assigned to a parameter format.

parametron—A digital circuit element utilizing the principle of parametric excitation. It is essentially a resonant circuit with a nonlinear reactive element that oscillates at half the driving frequency. The oscillation can be made to represent a binary digit by the choice between two stationary phases π radians apart.

paramistor—A digital logic circuit module containing several parametron elements.

paraphase amplifier—An amplifier that converts a single input signal into two out-of-phase signals for driving a push-pull stage.

parasite—Current in a circuit due to some unintentional cause such as inequalities of temperature or of composition; particularly troublesome in electrical measurement.

parasitic—An undesired low- or high-frequency signal in an electronic circuit.

parasitically excited—Said of an antenna element (such as a director or reflector) that is not directly connected to a source of rf energy, but instead is energized through radiation from a nearby element.

parasitic antenna—An antenna that is excited by radiation from other antennas rather than by electrical connection with them.

parasitic array—An antenna array containing one or more elements not connected to the transmission line.

parasitic components—In a monolithic integrated circuit, the capacitors and diodes that are formed between the planned circuit elements and the substrate during processing. The circuit design must allow for the functional effects of these parasitic components.

parasitic element—Also called passive element. 1. An antenna element (i.e., reflector, director, etc.) not connected to the transmission line or to any driven element. A parasitic element affects the gain and directivity pattern of an antenna, and also acts on a driven element by absorbing and returning energy from it. In a dipole reflector combination, the reflector is the parasitic element. 2. An element of a directional antenna that has no electrical connection to the active element(s) of the antenna, but which reflects or directs the radio waves so that they are additive along the directional axis. 3. An undesirable but inherent element in a circuit, such as wire resistance, core losses, winding capacitance, or leakage inductance.

parasitic field turn-on—See field inversion.

parasitic oscillation—1. An undesired self-sustaining oscillation at a frequency other than the operating frequency. Parasitic oscillations occur chiefly in vacuum-tube circuits. 2. Any undesired oscillation in an oscillator or amplifier stage.

parasitics—Parasitic oscillations.

parasitic suppressor—A parallel resistance, or a parallel combination of inductance and resistance, inserted into a grid or plate circuit to suppress parasitic oscillations.

paraxial ray—A ray that is parallel, or nearly parallel, to an optical axis.

PARD or pard—Acronym for *periodic and random deviation*, which replaces the term “ripple and noise.” 1. In an electronic power conversion unit, the periodic and random deviation of the output dc voltage, current, or power from its average value, with all external operational and environmental parameters maintained constant. The load impedance in particular must be held constant. Perturbations in the output that are induced by load impedance changes are dynamic load regulation or transient response. PARD may be defined as rms PARD or peak-to-peak PARD. 2. A broadband measurement of net ac variations in the dc output, usually measured within a 10- to 20-MHz bandwidth and expressed in millivolts rms. In a few special cases it is expressed as peak-to-peak variation.

parent population—Prototype or initial group of the articles under consideration.

parity—1. A method of checking the accuracy of binary numbers used in recorded, transmitted, or received data. An extra bit, called a parity bit, is added to a number. If even parity is used, the sum of all 1s in the number and its corresponding parity bit is always even. If odd parity is used, the sum of the 1s and the parity bit is always odd. 2. The number of 1s in a word (may be even or odd). When parity is used, an extra bit is used that indicates whether the data word has an odd or even number of 1s. ASCII uses seven bits for data and one bit for parity. Parity is one of the simplest error-detection techniques and will detect a single-bit failure. 3. A technique for testing transmitted data. Typically, a binary digit is added to the data to make the sum of all the digits of the binary data either always even (even parity) or always odd (odd parity). If any one bit is corrupted, the count will no longer agree and the error is detected.

parity bit—1. An additional bit used with a computer character or electronic channel data processor to provide a check for accuracy. 2. A binary digit appended to an array of bits to make the sum of all the bits always odd or always even. 3. An additional bit added to a memory word to make the sum of the number of 1s in a word always even (even parity) or always odd (odd parity). 4. A noninformation bit that is used to ensure that data has been transmitted accurately; a receiving device counts the “on” bits of every arriving byte; if odd parity is specified, an error condition will be flagged any time an even number of “on” bits is detected.

parity check—Synonymous with odd-even check. 1. An error-checking method that tests whether the number of 1s in a group of binary digits is odd or even. If a channel uses an odd parity scheme, an odd number of 1s implies that the data was received correctly, etc. 2. A technique used by the computer to check on the validity of data as it moves from one location to another. Parity for a given computer will be either even or odd; any data that contains an odd number of bits will be given one extra check bit in an even-parity computer. The computer can therefore recognize quickly whether any bit of information has been dropped or picked up as data has been moved. 3. A method of checking the correctness of binary data after that data has been transferred from or to storage. An additional bit, called the parity bit, is appended to the binary word or character to be transferred. The parity bit is the single-digit sum of all the binary digits in the word or character and its logical state can be assigned to represent either an even or an odd number of 1s making up the binary word. Parity is checked in the same manner in which it is generated. 4. The technique of detecting errors in a group of bits by adding a noninformation bit that will make the total number of 1s in the grouping either always even (even parity) or always odd (odd parity). 5. A check on the validity of a

binary word by determining whether the number of 1s in the word is odd or even.

parity checking—An error-detection technique in which character bit patterns are forced into parity, so that the total number of 1 bits is always odd or always even. This is accomplished by the addition of a 1 or 0 bit to each byte, as the byte is transmitted; at the other end of the transmission, the receiving device verifies the parity (odd or even) and the accuracy of the transmission.

parity checks and checksums—Methods of verifying that short sequences of bits are identical with the sequences originally transmitted.

parity error—An error occurring when the results of the parity calculations at the transmit and receive ends of a system don't agree.

parity tree—A group of exclusive OR gates that can be used to check a number of input bits for either odd or even parity. Parity trees are used both to check and generate parity wherever a redundant bit is added to a word in order to check for error.

part—1. The smallest subdivision of a system. 2. An item that cannot ordinarily be disassembled without destruction.

part failure—A breakdown that cannot be repaired and which ends the life of a part.

part-failure rate—The number of occasions, during a specified time period, on which a given quantity of identical parts will not function properly.

partial—1. A physical component of a complex tone. 2. A component of a sound sensation that can be distinguished as a simple tone that cannot be further analyzed by the ear and which contributes to the character of the complex sound.

partial carry—In parallel addition, a technique involving temporary storage of some or all of the carries instead of allowing them to propagate immediately.

partial dial tone—A high dial tone that notifies a calling party that he or she has not completed dialing within a specified period of time, or that not enough digits have been dialed.

partial motor—Also called a shell-type motor. A motor sold with rotor and stator only—no end bells and no containing frame.

partial node—The place in a standing-wave system at which some characteristic of the wave field has a minimum amplitude other than zero.

partial-read pulse—In a computer, any one of the applied currents that cause selection of a core for reading.

partial-select pulse—In a computer, the voltage response of an unselected magnetic cell produced by the application of partial-read pulses or partial-write pulses.

partial-write pulse—In a computer, any one of the applied circuits that cause a core to be selected for writing.

particle—An infinitesimal subdivision of matter—e.g., a molecule, atom, or electron.

particle accelerator—Any device for accelerating charged particles to high energies (e.g., cyclotron, betatron, Van de Graaff generator, linear accelerator).

particle orientation—The process by which acicular particles are positioned so that their longest dimensions tend to be parallel. Orientation is accomplished in magnetic tape by the combined effects of the sheer force applied during the coating process and a magnetic field applied to the coating while it is still fluid.

particles—Also known as domains. Small bits of oxide that are the recording media on magnetic tape. The smaller and more uniform they are, the better the tape's frequency response, provided they are evenly dispersed.

particle velocity—The velocity of a given infinitesimal part of a sound wave. The most common unit is centimeter per second.

partition—A portion of a hard disk with a size expressed in the disk sectors.

partitioning—Also called segmenting. 1. In a computer, subdividing a large block into smaller, more conveniently handled subunits. 2. Logical grouping of electrical functions within a given set of hardware components.

partition noise—A type of noise that appears in multielement vacuum tubes due to the random division of cathode current among the different electrodes. It has been called pseudoshot noise. It is more pronounced in pentodes and tetrodes than in triodes.

Part 95 rules—FCC rules and regulations governing the Citizens Radio Service.

part programmer—One who translates the physical operations for machining a part into a series of mathematical steps and then prepares the coded computer instructions for those steps.

parts density—The number of parts in a unit volume.

party line—A telephone line serving more than one subscriber, with discriminatory ringing for each. Usually either a two-party or a four-party line. Lines serving more than four parties are called rural lines.

Pascal—A block-structured high-level programming language in the style of ALGOL. It incorporates the control structures of structured programming (e.g., sequence, selection, repetition) and data structures (e.g., arrays, records, files, sets, and user-defined types). Named for the French physicist Blaise Pascal, it is in many ways simpler to use than BASIC. Pascal can be made machine-dependent or transportable.

pascal—The SI unit of pressure or stress. One pascal equals 1 newton per square meter. Letter symbol: Pa.

Paschen's law—The sparking potential between two terminals in a gas is proportional to the pressure times the spark length. For a given voltage, this means the spark length is inversely proportional to the pressure.

pass—One cycle of processing of a body of data.

passband—1. The band of frequencies that will pass through a filter with essentially no attenuation. 2. The frequency range in which a filter is intended to pass signals.

passband filters—Filters used in modem design to allow only the frequencies within the communication channel to pass, while rejecting all frequencies outside the channel.

passband ripple—In a filter, the difference, in decibels, between the minimum loss point and the maximum loss point in a specified bandwidth.

pass element—An automatic variable-resistance device, either a vacuum tube or power transistor, in series with the source of dc power. The pass element is driven by the amplifier error signal to increase its resistance when the output needs to be lowered or to decrease its resistance when the output must be raised. *See also* series regulator.

passivate—To treat the surface of a semiconductor with a relatively inert material in order to protect it from contamination.

passivated region—Any region covered by glass, SiO₂, nitride, or other protective material.

passivation—1. The growth of an oxide layer on the surface of a semiconductor to provide electrical stability by protecting the surface against moisture, contamination, particles, and mechanical damage. This reduces reverse-current leakage, increases breakdown voltages, and raises the power dissipation rating. 2. *See* glassivation. 3. A coating of electrically inert material, such as glass or silicon dioxide, used to protect semiconductors or resistors from environmental contamination. Unpassivated nickel-chromium resistors, for example, will open in the presence of water and a large applied dc potential. 4. The growth

of an oxide layer on the surface of a semiconductor to provide mechanical protection by isolating the transistor surface from electrical, mechanical (scratching of metal), and chemical conditions in the environment. 5. The technique of providing a semiconductor device chip with an isolating layer or "skin" that protects it from contamination by unwanted impurity atoms or molecules. With silicon devices, the isolating layer is usually composed of silicon dioxide (quartz) or silicon nitride, grown on the chip at a high temperature. 6. Electrolytical treatment of a metal or semiconductor to create a chemically bonded oxide layer on the surface to protect it from corrosion. 7. The formation of an insulating layer directly over a circuit or circuit element to protect the surface from contaminants, moisture, or particles. 8. Surface oxidation that acts as a barrier to further oxidation and corrosion.

passive—1. An inert component that may control, but does not create or amplify, energy. 2. Pertaining to a general class of device that operates on signal power alone. 3. Incapable of generating power or amplification. A nonpowered device that generally presents some loss to a system. 4. Describing a device that does not contribute energy to the signal it passes.

passive acoustic monitoring—The use of microphones and ancillary equipment to provide surveillance by monitoring the sounds in a protected premise.

passive communication satellite—A communication satellite that simply reflects a signal without amplification. In essence, it is a radio mirror. It requires a large reflecting surface and large, high-powered, complex ground stations.

passive component—1. A nonpowered component generally presenting some loss (expressed in decibels) to a system. 2. A component that has no gain characteristics, such as a capacitor or a resistor. 3. An electrical component without gain or current-switching capability. Commonly used when referring to resistors, capacitors, and inductors.

passive decoder—A device that is set so that only one specific reply code will pass a decoder and give an output from one decoder for display.

passive detection—Detection of a target by reception of signals emitted by the target rather than by means involving a signal source independent of the target.

passive device—1. A device that exhibits no transistance. It has no gain or control and does not require any input other than a signal to perform its function. Examples of passive devices are conductors, resistors, and capacitors. 2. A component that does not provide rectification, amplification, or switching, but reacts to voltage and current; e.g., resistor, capacitor. 3. An electronic component that does not require a bias voltage, e.g., a resistor, capacitor, or inductor.

passive electric network—An electric network with no source of energy.

passive element—1. A parasitic element. 2. A circuit element with no source of energy (e.g., a resistor, capacitor, inductor). 3. An electronic circuit element that displays no gain or control, such as a resistor or capacitor.

passive film circuit—A thin- or thick-film circuit network consisting entirely of passive circuit elements and interconnections.

passive homing system—A guidance system based on the sensing of energy radiated by the target. *See also* active homing; homing guidance.

passive intrusion sensor—A passive sensor in an intrusion alarm system that detects an intruder within the range of the sensor. Examples are a sound-sensing detection system, a vibration detection system, an infrared-motion detector, and an *E*-field sensor.

passive network—A network with no source of energy.

passive probe—A test probe that is constructed entirely of passive components—resistors, capacitors, and, in some cases, inductors.

passive pull-up—A gate output circuit in which the charging current for a load capacitance is obtained through a resistor.

passive reflector—A reflector often used on microwave relay towers to change the direction of a microwave. This permits convenient location of transmitter, repeater, and receiver equipment on the ground rather than at the tops of towers.

passive repeater—1. A radio-frequency device used to change the direction of a radio beam without amplification. 2. A large, flat metal or metal-screen surface that acts as a simple radio-frequency mirror.

passive satellite—A satellite that reflects, without amplification, communications signals from one ground station to another.

passive sensor—A sensor that detects natural radiation or radiation disturbances, but does not itself emit the radiation on which its operation depends.

passive solar energy—Energy gathered by natural convection and heating, rather than by mechanical means.

passive sonar—See sonar.

passive substrate—1. A substrate that may serve as a physical support and thermal sink for a thick- or thin-film integrated circuit but does not exhibit transistivity. Examples of passive substrates are glass, ceramic, alumina, etc. 2. A physical support and a thermal sink for circuits. The substrate itself performs no electrical function.

passive system—A system that emits no energy and therefore does not reveal its position or existence.

passive tracking system—Usually a system that tracks by reflected radiation from some external source, or by the jet emission of the vehicle (e.g., optical systems, use of commercial radio or television, reflection and infrared systems).

passive transducer—A transducer that does not require any local source of energy other than the received energy.

passive ultrasonic alarm system—An alarm system that detects the sounds in the ultrasonic frequency range caused by an attempted forcible entry into a protected structure. The system consists of microphones, a control unit containing an amplifier, filters, an accumulator, and a power supply. The unit's sensitivity is adjustable so that ambient noises or normal sounds will not initiate an alarm signal; however, noise above the preset level or a sufficient accumulation of impulses will initiate an alarm.

password—1. A code used to gain access to a locked system. Good passwords contain letters and non-letters and are not simple combinations. A good password might be "Bit@1*6." 2. A string of characters known (supposedly) only to the user of a particular computer account, employed to identify that person when he logs into the system. 3. A unique string of characters required to gain access to a device, data channel, computer, or data files. In multiple-user systems, users identify themselves with a password, unique to each user, before the computer will let them use the system.

paste—1. In batteries, the medium, in the form of a paste or jelly, containing an electrolyte. It is positioned adjacent to the negative electrode of a dry cell. In an electrolyte cell, the paste serves as one of the conducting plates. 2. Synonymous with *composition* and *ink* when relating to screenable thick-film materials.

paste blending—Mixing resistor pastes of different ohms per area value to create a third value in between those of the two original materials.

paste solder—1. Finely divided particles of solder suspended in a flux paste. Used for screening application onto a film circuit and reflowed to form connections to chip components. 2. A mixture of flux and finely divided solder.

PA system—Abbreviation for public-address system.

patch—1. To connect circuits together temporarily with a special cord known as a patch cord. 2. In a computer, to make a change or correction in the coding at a particular location by inserting transfer instructions at that location and by adding elsewhere the new instructions and the replaced instructions. This procedure is usually used during checkout. 3. The section of coding so inserted. 4. A group of instructions that have been inserted into a program to correct an error or deficiency. Patching a program rather than rewriting it is poor practice, for a program with numerous patches becomes very hard to understand.

patch bay—See jack bay.

patch board—A board or panel in which circuits are terminated in jacks for patch cords.

patch cable—A cable with plugs or terminals on each end of the conductor or conductors, used to temporarily connect circuits of equipment together.

patch cord—Sometimes called an attachment cord.

1. A short cord with a plug or a pair of clips on one end, for conveniently connecting two pieces of sound equipment such as a phonograph and tape recorder, an amplifier and speaker, etc. 2. A short audio cable with a male plug on each end. Commonly used for audio signal routing (patching) between nearby electronic devices, or between various jacks on a mixer or patch panel (patch bay). Patch cords often also route dc control signals as well as audio signals in electronic music synthesizers. 3. Cord, usually braid, with plugs or terminals on each end. Used to connect jacks or blocks in switchboards or programming systems. It is called a patch cord because it is used to temporarily "patch" a circuit.

patching—Connecting two lines or circuits together temporarily by means of a patch cord.

patching jack—A jack for interconnection of circuit elements.

patch panel—1. In a computer, a panel that contains means for changing circuit configurations; usually, it consists of receptacles into which jumpers can be inserted. 2. A panel where circuits are terminated and facilities provided for interconnecting between circuits by means of jacks and plugs.

path—1. In navigation, an imaginary line connecting a series of points in space and constituting a proposed or traveled route. 2. See channel, 2, 4, 5, 6, and 7.

path attenuation—The power loss between transmitter and receiver resulting from all causes.

pathfinding—The process of finding an idle path through a switching network, from entrance port to exit port.

path loss—Also known as space loss. The attenuation of a signal as it travels through space.

patient monitor—A system of instruments that permits remote monitoring at a central location in a hospital of such quantities as heart rate, blood pressure, temperature, etc.

pattern—1. The means of specifying the character of a wave in a guide. This is done by showing the loops of force existing in the guide for that wave. The pattern identifies the order and mode of the wave and the cross-sectional shape of the guide. 2. A geometrical figure representing the directional qualities of an antenna array.

3. The configuration of conductive and nonconductive materials on a panel or printed board. Also the circuit configuration on related tools, drawings, and masters.
4. The outline of a collection of circuit conductors and resistors that defines the area to be covered by the material on a film circuit substrate.

pattern definition—The accuracy, relative to the original artwork, with which pattern edges are reproduced in integrated-circuit elements.

pattern recognition—In a computer, the examination of records for certain code-element combinations.

pattern-sensitive fault—A fault that appears in response to some particular data pattern.

pause control—A feature of some tape recorders making it possible to temporarily stop the movement of the tape without switching the machine from the play or record position. (Essential for a tape recorder used for dictation and generally helpful for editing purposes.)

PAX or **pax**—Acronym for private automatic exchange. 1. An automatic system used exclusively for interoffice dial communications and having no trunks to the central office. 2. A dial telephone exchange that provides private telephone service to an organization.

pay-per-view—A method of purchasing television programming on a per-program basis.

paystation—A coin-operated telephone.

pay television—Also called subscription television.

1. A system whereby viewers must insert coins or record cards into a decoding device in order to view a television program that has been deliberately scrambled to prevent unpaid viewing. 2. A service that provides the TV viewer, for an extra monthly fee, with special extra programming such as first-run movies, sporting events, news, and features. 3. Generally refers to additional channel service—over and above regular TV-network cable service—in exchange for an extra monthly charge.

P-band—A radio-frequency band extending from 225 to 390 MHz and having wavelengths from 133.3 to 76.9 cm.

PBX or **pbx**—Abbreviation for private branch exchange. 1. A private telecommunications exchange that includes access to a public telecommunications exchange. 2. A telephone exchange, having a switchboard and associated equipment, that serves a single organization and usually is located on the customer's premises. It provides for switching calls between any two extensions served by the exchange or between any extension and the national telephone system via a trunk to a central office. 3. An intelligent, programmable switch that can route telephone calls or digital data from computers and terminals throughout a building or to an outside line for local or long-distance transmission.

pC—1. Letter symbol for picocoulomb.

pc—1. Abbreviation for program counter. 2. Abbreviation for phase corrector. A part of synchronous modems that adjusts the local data-clocking signal to match the incoming receive data sent by the remote clocking signal. 3. Abbreviation for printed circuit.

PC—1. Abbreviation for personal computer. Usually refers to an IBM-compatible microcomputer, but sometimes also is used to include Macintosh computers. 2. Abbreviation for programmable controller.

pcb—Abbreviation for printed circuit board.

PC-DOS—IBM's name for the disk operating system used in the IBM Personal Computer. (Similar to MS-DOS.)

p-channel—See PMOS.

p-channel device—A device constructed on an n-type silicon substrate, whose drain and source components are of p-type silicon. See also PMOS.

p-channel field-effect transistor or p-channel FET—A field-effect transistor that has a p-type conduction channel.

p-channel MOS—See PMOS.

PCM—1. Abbreviation for pulse-code modulation. 2. Abbreviation for punched card machine.

PCM/FM—Frequency modulation of a carrier by pulse-code-modulated information.

PCM/FM/FM—Frequency modulation of a carrier by subcarrier(s) that is (are) frequency modulated by pulse-code-modulated information.

PCM/PM—Phase modulation of a carrier by pulse-code-modulated information.

PCS—Abbreviation for Personal Communication Services. A term for digital low-power mobile telephone service.

PD—Abbreviation for photodetector.

P-display—See plan-position indicator.

PDM—Abbreviation for pulse-duration modulation.

PDM/FM—Frequency modulation of a carrier by pulses that are modulated in duration by information.

PDM/FM/FM—Frequency modulation of a carrier by subcarrier(s) that is (are) frequency modulated by pulses that are time duration modulated by information.

PDM/pm—Phase modulation of a carrier by pulses that are duration modulated by information.

PE—Abbreviation for phase encoded.

peak—Also called crest. 1. A momentary high amplitude level occurring in electronic equipment. 2. A momentarily high volume level during a radio program. It causes the volume indicator at the studio or transmitter to swing upward. 3. The maximum instantaneous value of a quantity. 4. To increase or sharpen the peaks of a waveform. 5. To broaden the frequency response of an amplifier by including inductors in its coupling networks so as to cancel the input and output capacitances of its active elements.

peak alternating gap voltage—In a microwave tube, the negative of the line integral of the peak alternating electric field, taken along a specified path across the gap.

peak amplitude—The maximum deviation (e.g., of a wave) from an average or mean position.

peak anode current—The maximum instantaneous value of an anode current in an electron tube.

peak-charge characteristic—The function giving the relation of one-half the peak-to-peak value of transferred charge in the steady state to one-half the peak-to-peak value of a specified symmetrical alternating voltage applied to a nonlinear capacitor.

peak coil current—The peak current through the ignition coil primary winding of an inductive system at the instant the contacts open.

peak current—1. The maximum current during a complete cycle. 2. Maximum amplitude of current an ionized device can pass without permanent change in breakdown ratings or published life specifications.

peak discharge energy—The maximum amount of energy a device can withstand during operation without permanent change in breakdown ratings or published life specifications.

peak distortion—The largest total distortion of signals noted during a period of observation.

peak electrode current—The maximum instantaneous current that flows through an electrode.

peak envelope power—Abbreviated PEP. 1. The power contained in the signal at the peak of the modulation envelope. 2. Of a radio transmitter, the average power supplied to the antenna transmission line by a transmitter during one radio-frequency cycle at the highest crest

of the modulation envelope, taken under conditions of normal operation.

peak firing temperature—The maximum temperature seen by the resistor or conductor paste in the firing cycle as defined by the firing profile.

peak flux density—The maximum flux density in a magnetic material.

peak forward anode voltage—The maximum instantaneous anode voltage in the direction a tube is designed to pass current.

peak forward-blocking voltage—The maximum instantaneous value of repetitive positive voltage that may be applied to the anode of an SCR with its gate circuit open.

peak forward drop—The maximum instantaneous voltage drop measured when a tube or rectifier cell is conducting forward current, either continuously or during transient operation.

peak indicator—A visual (light) indicator showing when transient signal levels exceed a recorder's ability to handle them without distortion. Such indicators are often used to supplement recording-level meters, which usually indicate average signal levels.

peaking—1. Adjusting a component so as to increase the response of a circuit at a desired frequency or band of frequencies. 2. To tune a circuit for a very sharp response at a particular frequency.

peaking circuit—A circuit capable of converting an input wave into a peaked waveform.

peaking control—In a television receiver, a fixed or variable resistor-capacitor circuit that controls the negative shape of the pulses originating at the horizontal oscillator. This is done to ensure a linear sweep.

peaking network—A type of interstage coupling network used to increase the amplification at the upper end of the frequency range. It consists of an inductance effectively in series (series peaking network) or shunt (shunt peaking network) with a parasitic capacitance.

peaking resistor—A resistor placed in series with the charging capacitor of the vertical sawtooth generator. By adding a negative peaking pulse to the sawtooth voltage, it creates the waveform required to produce a linear sawtooth current in the yoke.

peaking transformer—A transformer operated in such a way that its core is saturated in one direction or the other for most of a single ac cycle, with the result that the secondary voltage waveform is sharply peaked at each flux reversal. Sharpness of the peaking is enhanced by an approximately rectangular hysteresis loop in the core.

peak inverse anode voltage—The maximum instantaneous anode voltage in the direction opposite from that in which the tube is designed to pass current.

peak inverse voltage—The peak ac voltage that a rectifying cell or pn junction will withstand in the reverse direction.

peak level—The maximum instantaneous level that occurs during a specific time interval (i.e., in acoustics, the peak sound pressure level).

peak limiter—A device that automatically limits the magnitude of its output signal to approximate a preset maximum value by reducing its amplification when the instantaneous signal magnitude exceeds a preset value.

peak load—The maximum electrical power load consumed or produced in a stated period of time. It may be the maximum instantaneous load or the maximum average load over a designated interval of time.

peak magnetizing force—The upper or lower limiting value of a magnetizing force.

peak-or-valley readout memory—A circuit in which the output remains at the condition corresponding

to the most positive (least negative) or vice versa input signal since the circuit was set to initial conditions, until reset to those conditions.

peak plate current—The maximum instantaneous current passing through the plate circuit of a vacuum tube.

peak point—The point on the characteristic curve of a tunnel diode corresponding to the lowest voltage in the forward direction for which the differential conductance is zero.

peak-point emitter current—The maximum emitter current that can flow without allowing a UJT to go into the negative-resistance region.

peak power—1. The mean power supplied to the antenna of a radio transmitter during one radio-frequency cycle at the highest crest of the modulation envelope. 2. The maximum power of the pulse from a radar transmitter. Since the resting time of a radar transmitter is longer than its operating time, the average power output is much lower than the peak power. 3. Maximum instantaneous audio power available from a power amplifier.

peak power output—1. The output power averaged over the radio-frequency cycle having the maximum peak value that can occur under any combination of signals transmitted. 2. Maximum instantaneous power output from any power amplifier. Usually related to the saturation power of the amplifier.

peak pulse amplitude—The maximum absolute peak value of the pulse, excluding unwanted portions such as spikes.

peak pulse power—The maximum power of a pulse, excluding spikes.

peak-reading meter—1. A type of recording-level meter that responds to short transient signals. 2. A type of recording-level meter whose needle rises quickly and falls back at moderate speed, permitting the operator to judge the levels of transient peak waveforms.

peak response—The maximum response of a system to an input.

peak signal level—An expression of the maximum instantaneous signal power or voltage as measured at any point in a facsimile transmission system. This includes auxiliary signals.

peak sound pressure—The maximum absolute value of instantaneous sound pressure for any specified time interval. The most common unit is the microbar.

peak spectral emission—The wavelength at which the radiation from a lamp has the highest intensity.

peak speech power—The maximum instantaneous speech power over the time interval considered.

peak to peak—Abbreviated p-p. 1. The algebraic difference between the positive and negative maximum values of a waveform. 2. The amplitude (voltage) difference between the most positive and the most negative excursions (peaks) of an electrical signal.

peak-to-peak amplitude—The amplitude of an alternative quantity, measured from positive peak to negative peak. The sum of the absolute value of the peak positive and the peak negative excursions.

peak-to-peak output ripple—The periodic variations present in the output of a power supply. They have little effect on the average dc output but can clutter operation of circuits being powered.

peak-to-peak voltmeter—A voltmeter that indicates the overall difference between the positive and negative voltage peaks.

peak value—Also called crest value. 1. The maximum instantaneous value of a varying current, voltage, or power. For a sine wave, it is equal to 1.414 times the effective value of the sine wave. 2. The largest instantaneous amplitude of a waveform.

peak voltage—The maximum value present in a varying or alternating voltage. This value may be either positive or negative.

Peak voltage.

peak voltmeter—A voltmeter that reads peak values of an alternating voltage.

peak wavelength—The wavelength at the peak of the radiated spectrum of an emitter.

pea lamp—An incandescent lamp with a bulb about the size of a pea. Its small size makes it ideal for use by doctors, on instrument panels, and in small flashlights.

pedal clavier—In an organ, the pedal keyboard that supplies the bass accompaniment for the other manuals.

pedal keyboard—See pedal clavier.

pedestal—1. A substantially flat-topped pulse that elevates the base level for another wave. 2. The base of a radar antenna.

pedestal level—See blanking level.

pedestal pulse—A square-wave pulse or gate on which a video signal or sweep voltage may be superimposed.

peek-a-boo—In a computer, a method of determining the presence or absence of holes in identical locations on punched cards by placing one card on top of another. See also Batten system.

peel strength (peel test)—A measure of adhesion between a conductor and the substrate. The test is performed by pulling or peeling the conductor off the substrate and observing the force required.

peel-strength adhesion—See bond strength.

peg-count meters—In telephone practice, meters or registers used to indicate the number of trunks tested, circuits passed busy, test failures, and repeated tests completed.

pel—Contraction of the phrase picture element; synonymous with pixel.

pellicle—A thin membrane that has the capability of splitting beams, polarizing light, and reflecting images with few or no optical side effects.

Peltier coefficient—The quotient of the rate of Peltier heat absorption by the junction of two dissimilar conductors divided by the current through the junction. The Peltier coefficient of a couple is the algebraic difference between either the relative or absolute Peltier coefficients of the two conductors making up the couple.

Peltier effect—The production or absorption of heat at the junction of two metals when current is passed through the junction. Reversing the direction of the current changes a production of heat to an absorption, and vice versa.

Peltier electromotive force—1. The component of voltage produced by a thermocouple after being heated by the Peltier effect at the junction of the different metals. It adds to the Thomson electromotive force to produce the

total voltage of the thermocouple. 2. The boundary emfs produced across the junctions of two different metals. Associated with the heating and cooling effects of the two junctions.

Peltier heat—The thermal energy absorbed or produced as a result of the Peltier effect.

pen centering—An electrical or mechanical adjustment by which an oscillator pen is positioned to channel center.

pencil beam—A radar beam in which the energy is confined to a narrow center.

pencil-beam antenna—A unidirectional antenna in which those cross sections of the major lobe perpendicular to the maximum radiation are approximately circular.

pencil tube—A small vacuum tube designed for operation in the ultrahigh-frequency band and used as an oscillator or rf amplifier.

pendant—The type of plug and/or receptacle that is not mounted in a fixed position or attached to a panel or side of equipment.

pendant station—A push-button station suspended from overhead and connected by means of flexible cord or conduit, but supported by a separate cable.

pendulous accelerometer—A device that measures linear accelerations by means of a restrained unbalanced mass. Two pivots and jewels support the unbalanced gimbal, and the torsion bar functions as the spring.

penetrating frequency—See critical frequency.

penetration depth—1. In induction heating, the effective depth of the induced current. The skin effect causes this to be nearer the surface with high frequencies than with low frequencies. 2. The extent to which an external magnetic field penetrates a superconductor.

Penning discharge—A type of discharge in which electrons are forced to oscillate between two opposed cathodes and are prevented from going to the surrounding anode by the presence of a magnetic field. It is sometimes referred to as a pig discharge because the device producing it was first used as an ionization gage called the Penning Ionization Gage.

Penning Ionization Gage—See Penning discharge.

pen plotter—A recorder specifically designed for computer graphics that may be used online, remote batch, or in a time-sharing environment. The plotter will yield reproducible records of graphs, charts, and drawings on plain paper annotated with alphanumerics.

pen position—An electrical or mechanical adjustment by which an oscillograph pen is positioned to any desired amplitude grid mark on the chart to represent zero signal.

pent—Abbreviation for pentode.

Pentaconta switching system—Trade-marked designation of an ITT common-controlled electromechanical telephone switching system that uses relays and cross-bar switches.

pentagrid converter—A pentagrid vacuum tube used as a combination oscillator and mixer in a superheterodyne receiver.

Pentagrid converter.

pentagrid mixer—A pentagrid vacuum tube used to mix the rf and local-oscillator signals in a superheterodyne receiver.

pentagrid tube—An electron tube having five grids, plus an anode and a cathode.

pentatron—A five-electrode vacuum tube that provides push-pull amplification with a single tube. It has one cathode, two grids, and two anodes. In effect, it is two tubes in one.

pentode—A five-electrode vacuum tube containing an anode, a cathode, a control electrode, and two grids.

pentode field-effect transistor—A five-lead transistor with three gates. It can be connected like a pentode if each of the gates is supplied from an independent bias source.

pentode transistor—A point-contact transistor in which there are four point-contact electrodes; the body serves as a base, and there are three emitters and one collector.

PEP—Abbreviation for peak envelope power.

perceived noise level—An empirical measure that includes allowance for the subjective reaction of people to noise in the various frequency ranges. It is expressed in decibels (PNdB).

percentage differential relay—A differential relay that functions when the difference between two quantities of the same nature exceeds a fixed percentage of the smaller quantity. This term includes relays formerly known as ratio-balance relays, biased relays, and ratio-differential relays.

percentage modulation—*See* percent of modulation.

percentage of meter accuracy—The ratio of the actual meter reading to the true reading, expressed as a percent.

percentage ripple—*See* percent of ripple voltage.

percentage supervision—A method of line supervision in which the current in, or resistance of, a supervised line is monitored for changes. When the change exceeds a selected percentage of the normal operating current or resistance in the line, an alarm signal is produced.

percentage sync—Ratio of the amplitude of the synchronizing signal to the peak-to-peak amplitude of the picture signal between blanking and reference white level, expressed in percent.

percentage timer—A repeat-cycle non-reset timer with fixed cycle length, having a dial adjustment of the percentage of the cycle time for which the contacts are operated.

percent break—The period of time, expressed as a percentage, that a dial circuit stands open compared to the total time of the dial signals.

percent conductivity—Conductivity of a material expressed as a percentage of that of copper.

percent make—1. In pulse testing, the length of time a circuit is closed compared to the duration of the test signal. 2. The portion (in percent) of a pulse period during which telephone-dial pulse springs make contact.

percent-modulation meter—An instrument that indicates the modulation percentage of an amplitude-modulated signal, either on a meter or a cathode-ray tube.

percent of deafness—*See* percent of hearing loss.

percent of harmonic distortion—A measure of the harmonic distortion in a system or component. It is equal to 100 times the ratio of the square root of the sum of the squares of the root-mean-square harmonic voltages (or currents) to the root-mean-square voltage (or current) of the fundamental.

percent of hearing—At a given frequency, 100 minus the percent of hearing loss at that frequency.

percent of hearing loss—Also called percent of deafness. At a given frequency, 100 times the ratio of the hearing loss in decibels to the number of decibels between the normal threshold levels of audibility and feeling.

percent of modulation—1. In AM, the ratio of half the difference between the maximum and minimum amplitudes, expressed in percentage. 2. In FM and TV audio transmission, the ratio of the actual frequency swing to the frequency swing defined as 100-percent modulation, expressed in percentage. For FM broadcast stations, a frequency swing of ± 75 kHz is defined as 100-percent modulation. For television, it is ± 25 kHz.

percent of ripple voltage—Ratio of the effective (root-mean-square) value of the ripple voltage to the average value of the total voltage, expressed in percent.

percent of syllabic articulation—*See* syllable articulation.

percent ripple (rms)—The ratio of the effective (rms) value of the ripple voltage, expressed in percent. The new term is PARD.

perceptron—A system capable—either in theory or in practice—of performing knowledgeable functions such as recognition, classification, and learning. These functions may exist as mathematical analyses, computer programs, or hardware.

percussion—Musical sounds characterized by sudden or sharp transients. Organ percussion is achieved by causing the tone to start to decay the instant it is played rather than waiting until the key is released.

percussive arc welding—A process in which the surfaces to be welded are held at a fixed gap while rf energy is applied. This ionizes the air gap between the two surfaces, causing the air gap to become a conductor. When the air gap is conductive, a capacitor bank dumps a controlled amount of energy into the system for a controlled time period. This results in an electric arc that scarifies the surfaces to be welded and heats them to welding temperature. As the pulse from the capacitor bank decays, a mechanical system drives the two hot surfaces together, consummating the weld.

perfect dielectric—Also called ideal dielectric. A dielectric in which all the energy required to establish the electric field in it is returned to the electric system when the field is removed. A perfect dielectric has zero conductivity and exhibits no absorption phenomena. A vacuum is the only known perfect dielectric.

perforated tape—*See* punched tape.

perforator—In telegraphy, a device that punches code signals into paper tape for application to a tape transmitter.

performance—Degree of effectiveness of operation.

performance characteristic—A characteristic measurable in terms of some useful denominator—e.g., gain, power output, etc.

perimeter alarm system—An alarm system that provides perimeter protection.

perimeter protection—Protection of access to the outer limits of a protected area, by means of physical barriers, sensors on physical barriers, or exterior sensors not associated with a physical barrier.

period—Sometimes called periodic time. 1. The time required for one complete cycle of a regular, repeating signal, function, or series of events. 2. The time between two consecutive transients of the pointer or indicating means of an electrical indicating instrument in the same direction through the rest position. 3. The time elapsing between two consecutive passages of a satellite through a characteristic point on its orbit. 4. Of an underdamped instrument, the time required, following an abrupt change in the measurand, for the pointer or other indicating means

to make two consecutive transits in the same direction through the rest position.

periodic—Repeating itself regularly in time and form.

periodic antenna—An antenna in which the input impedance varies as the frequency does (e.g., open-end wires and resonant antennas).

periodic current—Oscillating current, the values of which recur at equal time intervals.

periodic damping—Also called underdamping. Damping in which the pointer of an instrument oscillates about the final position before coming to rest. The point of change between periodic and aperiodic damping is called critical damping.

periodic duty—Intermittent duty in which the load conditions recur at regular intervals.

periodic electromagnetic wave—A wave in which the electric field vector is repeated in detail—either at a fixed point, after a lapse of time known as the period; or at a fixed time, after the addition of a distance known as the wavelength.

periodic electromotive force—An oscillating electromotive force that repeats its sequence of values over equal intervals of time.

periodicity—The variations in the insulation diameter of a transmission cable that result in reflections of a signal when its wavelength or a multiple thereof is equal to the distance between two diameter variations.

periodic line—A line consisting of identical, similarly oriented sections, each section having nonuniform electrical properties.

periodic PARD—Pertains to that portion of the total PARD in an electronic power supply whose frequency is identical or harmonically related to the input frequency and/or intentionally internally generated signal frequencies. This phenomenon is frequently referred to as ripple.

periodic pulse train—A pulse train made up of identical groups of pulses repeated at regular intervals.

periodic quantity—An oscillating quantity in which any value it attains is repeated at equal time intervals.

periodic rating—The load that can be carried for the alternate periods of load and rest specified in the rating without exceeding the specified heating limits.

periodic resonance—Also called natural resonance. Resonance in which the applied agency maintaining the oscillation has the same frequency as the natural period of oscillation in a system.

periodic time—See period.

periodic vibration—1. A vibration having a regularly recurring waveform, e.g., sinusoidal vibration. 2. An oscillator motion whose amplitude pattern repeats after fixed increments of time.

periodic wave—1. Wave in which the displacement has a periodic variation with time, distance, or both. 2. A wave that repeats itself at regular intervals of time.

peripheral—1. Having to do with a device by means of which a computer communicates to the outside world. Auxiliary memories, such as tape, disk, and drum, may also be considered to be peripheral devices. 2. Any external device used in a computer system. 3. A device used to extend the operation of a computer, either with regards to functionality or capacity. Peripherals are connected to the central processor of a computer system by appropriate data paths. 4. Any human interface device connected to a computer. 5. A noncomputing input or output device, external to the CPU and main memory of a computer but connected by the appropriate electrical connections, thus allowing the computer to perform various external functions.

peripheral bus—For a computer, a dedicated bus for high-speed transfer of blocks of data between a system and its peripherals, including tape and disk drives.

peripheral control unit—An intermediary control device that links a peripheral unit to the central processor, or, in the case of offline operation, to another peripheral unit.

peripheral device—1. Any instrument or machine that enables a computer to communicate with the outside world or that otherwise aids the operation of the computer, but does not form part of the basic installation. 2. A general term designating various kinds of machines that operate in combination or conjunction with a computer but are not physically part of the computer. Peripheral devices typically display computer data, store data from the computer and return the data to the computer on demand, prepare data for human use, or acquire data from a source and convert it to a form usable by a computer. Peripheral devices include printers, keyboards, graphic display terminals, paper tape reader/punches, analog-to-digital converters, disks, and tape drives. 3. Any device distinct from the computer that can provide input to and/or accept output from the computer.

peripheral electron—Also called a valence electron. One of the outer electrons of an atom. Theoretically, it is responsible for visible light, thermal radiation, and chemical combination.

peripheral equipment—1. In a data processing system, any unit of equipment, distinct from the central processing unit, that may provide the system with outside communication. 2. Equipment that is external to and not a part of the central processing instrumentation. Includes such equipment as tape punches and readers, magnetic tape or disk storage units, digital printers, graphic recorders, and typewriters. 3. Equipment used in connection with or attached to electronic computers. This includes typewriters, calculators and accounting machines, cash registers, tape readers, and similar devices. 4. Units that may communicate with the programmable controller, but are not part of the programmable controller, e.g., Teletype, cassette recorder, CRT terminal, tape reader, etc. 5. Equipment that works in conjunction with a computer or a communication system but is not a part of it. 6. Machines such as card readers, magnetic tape units, fast driver scanners, and other equipment bearing a similar working relationship to the computing device. In general they can be considered a sink and source of information external to the information process.

peripheral processor—A general term for a laser computer associated with a large machine. Among the functions may be multiplexing, data formatting, concentrating, polling, and the handling of simple routines to increase the capacity of a communications channel or relieve the main (often called host) computer.

peripherals—Accessory parts of a computer system not considered essential to its operation, such as printers and modems.

peripheral transfer—The transmission of data between two peripheral units.

peripheral units—Equipment that works in conjunction with a data terminal or computer but is not a part of that unit, such as cards, paper-tape readers, punches, or keyboards.

periphonic system—See ambisonic reproduction.

Permalloy—A high-permeability magnetic alloy composed mainly of iron and nickel.

permanent circuit—An alarm circuit that is capable of transmitting an alarm signal whether the alarm control is in access mode or secure mode. Used, for example, on foil fixed windows, tamper switches, and

supervisory lines. *See also* permanent protection; supervised lines; supervisory alarm system; supervisory circuit.

permanent echo — Signal received and displayed by a radar, indicating reflections from fixed objects.

permanent-field synchronous motor — A type of synchronous motor in which the member carrying the secondary laminations and windings also carries permanent-magnet field poles that are shielded from the alternating magnetic flux by the laminations. It behaves as an induction motor when starting but runs at synchronous speed.

permanent magnet — Abbreviated pm. A piece of hardened steel or other magnetic material that has been so strongly magnetized that it retains the magnetism indefinitely.

permanent-magnet centering — Vertical or horizontal shifting of a television picture by means of magnetic fields from permanent magnets mounted around the neck of the picture tube.

permanent-magnet focusing — 1. Focusing of the electron beam in a television picture tube by means of one or more permanent magnets located around the neck. 2. The focusing of an electron beam by a magnetic field that permanently retains the majority of its magnetic properties.

permanent-magnet material — Ferromagnetic material that, once having been magnetized, resists external demagnetizing forces (i.e., requires a high coercive force to remove the magnetism).

permanent-magnet motor — A direct-current motor that has a permanent magnet field (stationary member) and a wound armature (rotating member). Its speed can be changed by varying the armature voltage.

permanent-magnet moving-coil instrument — Also called D'Arsonval instrument. An instrument in which a reading is produced by the reaction between the current in a movable coil or coils and the field of a fixed permanent magnet.

Permanent-magnet moving-coil instrument.

permanent-magnet moving-iron instrument — Also called polarized-vane instrument. An instrument in which a reading is produced by an iron vane as it aligns itself in the magnetic field produced by a permanent magnet and by the current in an adjacent coil of the instrument.

permanent-magnet speaker — A moving-conductor speaker in which the steady magnetic field is produced by a permanent magnet.

Permanent-magnet speaker.

permanent-magnet stepping motor — A type of motor in which a permanent magnet serves as the rotor. Current is switched sequentially through different stator coils, and the rotor aligns itself with the energized stator poles.

permanent magnistor — A saturable reactor that has the properties of memory and the ability to handle appreciable power.

permanent memory — A type of storage device that retains data intact when the computer has been shut down.

permanent-memory computer — A computer in which the stored information remains intact even after the power has been turned off.

permanent protection — A system of alarm devices, such as foil, burglar alarm pads, or lacing, connected in a permanent circuit to provide protection whether the control unit is in the access mode or secure mode.

permanent set — The deformation that remains in a specimen after it has been stressed in tension for a definite time interval and released for a definite time interval.

permanent storage — A computer storage device that retains the stored data indefinitely.

permatron — A thermionic gas diode, the discharge of which is controlled by an external magnetic field. It is used mainly as a controlled rectifier and functions like a thyatron.

permeability — Symbolized by the Greek letter mu (μ). The measure of how much better a given material is than air as a path for magnetic lines of force. (Air is assumed to have a permeability of 1.) It is equal to the magnetic induction (B) in gauss divided by the magnetizing force (H) in oersteds.

permeability tuning — A method of tuning a circuit by moving a magnetic core into or out of a coil to vary its inductance.

permeameter — An apparatus for determining the magnetizing force and flux density in a test specimen. From these values, the normal induction curves or hysteresis loops can then be plotted and the magnetic permeability computed.

permeance — The ratio of the flux through any cross section of a tabular portion of a magnetic circuit bounded by the lines of force and by two equal potential surfaces to the magnetic potential of the difference between the surfaces, taken within the portion under consideration. Permeance is the reciprocal of reluctance and can be considered analogous to electrical conductance. In the cgs system it is equal to the magnetic flux (in maxwells) divided by the magnetomotive force (in gilberts).

permeance coefficient—Also called demagnetizing coefficient. Describes operating conditions of a magnet and is the slope of the magnetic load line.

permissive control device—Generally a two-position, manually operated switch that in one position permits the closing of a circuit breaker or the placing of an equipment into operation, and in the other position prevents the circuit breaker or the equipment from being operated.

permittivity—1. See dielectric constant. 2. That property of a dielectric which determines the electrostatic energy stored per unit volume for a unit potential gradient.

permutation modulation—Proposed method of transmitting digital information by means of additive white Gaussian noise. Pulse-code modulation and pulse-position modulation are considered simple special cases of permutation modulation.

permutation table—In computers, a table for use in the systematic construction of code groups. It may also be used in the correction of garbles in groups of code text.

peroxide of lead—A lead compound that forms the principal part of the positive plate in a charged lead-acid cell.

perpendicular magnetization—In magnetic recording, magnetization that is perpendicular to the line of travel and parallel to the smallest cross-sectional dimension of the medium. Either single- or double-pole-piece magnetic heads may be used.

persistence—1. The length of time a phosphor dot glows on the screen of a cathode-ray tube before going out; i.e., the length of time it takes to decay from initial brightness (reached during fluorescence) until it can no longer be seen. 2. In a cathode-ray tube, the period that a phosphor continues to glow after excitation is removed.

persistence characteristic (of a luminescent screen)—Also called the decay characteristic. The relationship (usually shown by a graph) between the time a luminescent screen is excited and the time it emits radiant power.

persistence of vision—The physiological phenomenon whereby the eye retains a perception of an image for a short time after the field of vision has disappeared.

persistent current—A current that is magnetically induced and flows undiminished in a superconducting material or circuit.

persistor—A bimetallic circuit used for storage or readout in a computer. It is operated near absolute zero, and changes from a resistive to a superconductive state at a critical current value.

persistron—A device in which electroluminescence and photoconductivity are combined into a single panel capable of producing a steady or persistent display with pulsed signal input.

personal computer—Abbreviated PC. 1. A micro-computer that is designed to be used by a single user. 2. Self-contained, relatively small computer for individual users that contains all the hardware and software necessary to perform the required task(s).

persuader—In a storage tube, an element that directs secondary emission toward the electron-multiplier dynodes.

PERT—Acronym for program evaluation and review technique. A management tool for comparing actual with scheduled progress of a program.

perveance—The space-charge-limited cathode current divided by the three-halves power of the anode voltage in a diode.

petalized dish—A parabolic satellite signal receiving dish that is shipped in sections, or petals, and assembled at the installation site.

petticoat insulator—An insulator having an outward flaring lower part that is hollow to increase the length of the surface leakage path and keep part of the path dry at all times.

pF—Letter symbol for picofarad.

pg—Abbreviation for power gain.

p-gate thyristor—A thyristor in which the gate terminal is connected to the p-region nearest the cathode and which is normally switched to the on state by applying a positive signal between the gate and cathode terminals.

pH—A measure of the degree of acidity or alkalinity of a solution. In a neutral solution the pH value is 7. In acid solutions it ranges from 0 to 7, and in alkaline solutions it ranges from 7 to 14.

phanastron—An electronic circuit of the multivibrator type that is normally used in the monostable form. It is a stable trigger generator in this connection and is used in radar systems for gating functions and sweep-delay functions.

phanotron—A term used primarily in industrial electronics to mean a hot-cathode gas diode.

phantom—A signal derived from two sources in such a way as to appear located from a third source. Stereo signals “appearing” between speakers are said to be phantom.

phantom channel—In a stereo system, an electrical combination of the left and right channels fed to a third, centrally located speaker.

phantom circuit—A superimposed circuit derived from two suitably arranged pairs of wires called side circuits. Each pair of wires is a circuit itself, and at the same time acts as one conductor of the phantom circuit.

phantom-circuit loading coil—A loading coil that introduces the desired amount of inductance into a phantom circuit and a minimum amount into the constituent side circuits.

phantom-circuit repeating coil—A repeating coil used at a terminal of a phantom circuit, in the terminal circuit extending from the midpoints of the associated side-circuit repeating coils.

phantom coil—A coil originally used in a phantom circuit for impedance matching. Most generally, any coil, side or phantom, in a phantom circuit. When the term is used, the meaning should be made clear.

phantom group—1. A group of four open-wire conductors suitable for the derivation of a phantom circuit. 2. Three circuits that are derived from simplexing two physical circuits to form a phantom circuit.

phantom OR and AND—See wired OR.

phantom repeating coil—A side-circuit repeating coil or a phantom-circuit repeating coil, when discrimination between these two types is not necessary.

phantom signals—Signals appearing on the screen of a cathode-ray-tube indicator; their cause cannot readily be determined, and they may be due to circuit fault, interference, propagation anomalies, jamming, etc.

phantom target—See echo box.

phase—1. The angular relationship between current and voltage in alternating-current circuits. 2. The number of separate voltage waves in a commercial alternating-current supply (e.g., single-phase, three-phase, etc.). Symbolized by the Greek letter *phi* (ϕ). 3. In a periodic function or wave, the fraction of the period that has elapsed, measured from some fixed origin. If the time for one period is represented as 360° along a time axis, the phase position is called phase angle. 4. The relative timing of a signal in relation to another signal; if both signals occur at the same instant, they are in phase; if they occur at different instants, they are out of phase. 5. That part of a period through which the independent variable

has advanced, as measured from an arbitrary origin. 6. A particular stage, or point of advancement, in an electrical cycle. The fractional part of the period through which the time has advanced, measured from some arbitrary point, usually expressed in electrical degrees, where 360° represents one cycle. 7. The difference between the zero crossing or starting reference point between a standard waveform and the measured waveform. Phase is usually measured in degrees.

phase advancer—A phase modifier that supplies leading reactive volt-amperes to the system to which it is connected. Phase advancers may be either synchronous or nonsynchronous.

phase angle—1. Of a periodic function, the angle obtained by multiplying the phase by 2π if the angle is to be expressed in radians, or 360 for degrees. 2. The angle between the vectors representing two periodic functions that have the same frequency. 3. The phase difference, in degrees, between corresponding stages of progress of two cyclic operations. 4. The angle between two vectors that represent two simple periodic quantities that vary sinusoidally and that have the same frequency. 5. A notation for phase position when the period is denoted as 360.

phase-angle correction factor—That factor by which the reading of a wattmeter or watt-hour meter operated from the secondary of a current or potential transformer, or both, must be multiplied to correct for the effective phase displacement of current and voltage due to the measuring apparatus.

phase-angle measuring relay—Also called out-of-step protective relay. A device that functions at a predetermined phase angle between two voltages or currents, or between voltage and current.

phase-angle meter—See phase meter.

phase angle of a current transformer—The angle between the primary current vector and the secondary current vector reversed. This angle is conveniently considered as positive when the reversed secondary current vector leads the primary current vector.

phase angle of a potential (voltage) transformer—The angle between the primary voltage vector and the secondary voltage vector reversed. This angle is conveniently considered as positive when the reversed secondary voltage vector leads the primary voltage vector.

phase anomaly—A sudden irregularity in the phase of a low-frequency or very low frequency signal.

phase balance—In a chopper, the phase-angle difference between positive and negative halves of the square wave; the difference in degrees between 180° and the measured angle between square-wave midpoints.

phase-balance current relay—See reverse-phase current relay.

phase-balance relay—A relay that functions by reason of a difference between two quantities associated with different phases of a polyphase circuit.

phase center (center of radiation)—Pertaining only to antenna types that have radiation characteristics such that while they are radiating energy, one can observe the antenna from a distance of many wavelengths and see the energy radiating from a point within the antenna array. The position of a point-source radiator that would replace the antenna and produce the same far-field phase contour.

phase characteristic—A graph of phase shift versus frequency, assuming sinusoidal input and output.

phase comparator—See phase detector.

phase-comparison tracking system—A system that provides target-trajectory information by the use of cw phase-comparison techniques.

phase-compensation network—A network used to provide closed-loop stability in an operational amplifier. No greater than 12-dB/octave rolloff of the open-loop gain is allowed.

phase conductors—Those conductors other than the neutral conductor of a polyphase circuit.

phase constant—1. The imaginary component of the propagation constant. For a traveling plane wave at a given frequency, the rate in radians per unit length at which the phase lag of a field component (for the voltage or current) increases linearly in the direction of propagation. 2. With respect to a traveling plane wave at a known frequency, the space rate of decrease of phase of a field component in the direction of propagation, measured in radians per unit length.

phase control—Also called horizontal parabola control. 1. One of three controls for adjusting the phase of a voltage or current in a color television receiver employing the magnetic-convergence principle. Each control varies the phases of the sinusoidal voltages applied, at the horizontal-scanning frequency, to the coils of the magnetic-convergence assembly. 2. A technique for proportional control of an output signal by conduction only during certain parts of the cycle of the ac line voltage. 3. A method of regulating a supply of alternating current by use of a switching device such as a thyristor, by varying the point in each ac cycle or half-cycle at which the device is switched on.

phase-controlled rectifier—A rectifier circuit in which the rectifying element is a thyatron having a variable-phase sine-wave grid bias.

phase correction—The process of keeping synchronous telegraph mechanisms in substantially correct phase relationship.

phase corrector—1. A network designed to correct for phase distortion. 2. See pc, 2.

phased array—1. A group of simple radiating elements arranged over an area called an aperture. A beam (or beams) can be formed by superposition of the radiation from all the elements, and the direction of the beam can be adjusted by varying the relative phase of the signal applied to each element or by varying the frequency of the main oscillator. 2. An antenna consisting of a plurality of individual antennas, called elements, that are arrayed in a grid and interconnected so that a specific phase relationship exists between them, forming a narrow beam pattern for the reception of electromagnetic signals. 3. A technique of improving the gain of an antenna system by combining the outputs of several similar VHF/UHF/FM antennas in an array in such a way that the output signals from each one are exactly in phase with one another.

phase delay—1. In the transfer of a single frequency wave from one point to another in a system, the delay of part of the wave identifying its phase. 2. The insertion phase shift (in cycles) divided by the frequency (in cycles per second, or hertz). See also delay distortion, 2.

phase-delay distortion—The difference between the phase delay at one frequency and the phase delay at a reference frequency.

phase detector—Also called phase discriminator or phase comparator. 1. A TV circuit in which a dc correction voltage is derived to maintain a receiver oscillator in sync with some characteristic of the transmitted signal. 2. A circuit that detects both the magnitude and the sign of the phase angle between two sine-wave voltages or currents. 3. A circuit that creates an output level which is a function of the phase angle between two ac input signals. Most phase detectors are also amplitude sensitive. 4. A circuit that compares the relative phase between two inputs and produces an error voltage dependent on the difference. This error voltage corrects the VCO frequency

during tracking. Sometimes called a phase comparator or mixer. 5. In both digital and analog phase-locked loops, a circuit that compares the input with the signal from either a VCO (analog) or a divide-by-*n* counter (digital) and generates an error voltage based on the phase difference. The error signal corrects the VCO frequency (analog) or controls the direction of an up/down counter (digital).

phase-detector gain factor—In analog devices, the conversion factor relating the phase detector output voltage and the phase difference between the input and voltage-controlled oscillator (VCO) signals. In digital phase-locked loops, the output of a divide-by-*n* counter is compared with the input signal, since digital chips do not use VCOs.

phase deviation—In phase modulation, the peak difference between the instantaneous phase angle of the modulated wave and the phase angle of the sine-wave carrier, both expressed in radians or degrees.

phase difference—The time in electrical degrees by which one wave leads or lags another.

phase discriminator—See phase detector.

phase distortion—The alteration of a complex waveform produced as it passes through a network or transducer whose phase shift is a function of frequency. See also phase-frequency distortion.

phase-distortion coefficient—In a transmission system, the difference between the maximum and minimum transit times for frequencies within a specified band.

phase encoded—Abbreviated PE. A method of magnetic recording in which the phase of a flux reversal determines the binary content.

phase equalizer—A circuit employed to neutralize the effect of phase-frequency distortion in a particular range of frequencies.

phase-frequency distortion—Also called phase distortion. Distortion that occurs when the phase shift is not directly proportionate to the frequency over the range required for transmission, or the effect of such departure on a transmitted signal.

phase hits—Abrupt shifts in the phase of a transmitted carrier. Excessive phase hits can cause errors in high-speed phase-modulated modems. Phase hits generally originate in radio carrier systems.

phase inversion—The condition whereby the output of a circuit produces a wave of the same shape and frequency but 180° out of phase with the input.

phase inverter—1. A stage that functions chiefly to change the phase of a signal by 180°, usually for feeding one side of a following push-pull amplifier. 2. See vented baffle. 3. A network or device such as a paraphrase amplifier, which produces two output signals that differ in phase by half a cycle.

phase jitter—1. An analog-line impairment caused by power and communication equipment along the line that shifts the signal phase relationship back and forth. 2. Peak-to-peak phase deviation (expressed in degrees) of a transmitted carrier signal. An excessive phase jitter causes errors in high-speed phase-modulated modems. Phase jitter generally originates in frequency-division multiplexers in carrier systems.

phase localizer—An airfield runway localizer in which lateral guidance is obtained by comparing the phases of two signals.

phase lock—The technique of making the phase of an oscillator signal follow exactly the phase of a reference signal by comparing the phases between the two signals to adjust the frequency of the reference oscillator.

phase-locked loop—Abbreviated pll or PLL. 1. A communications circuit in which a local oscillator is synchronized in phase and frequency with a received signal. 2. A closed-loop electronic servomechanism whose

output locks onto and tracks a reference signal. Phase lock is accomplished by comparing the phases of the output signal (or a multiple of it) and the reference signal. Any phase difference between these signals is converted into a correction voltage that causes the phase of the output signal to change so that it tracks the reference. 3. A closed-loop system, consisting of a phase detector, a filter, and a voltage-controlled oscillator. The phase detector provides an error signal that locks the voltage-controlled oscillator to the frequency of an incoming signal. 4. A circuit whose output locks onto and tracks a reference signal. Phase locking is accomplished by comparing the phases of the output signal and the reference signal, and then converting any difference into a correction voltage that changes the phase of the output so it matches that of the reference or input signal. 5. An electronic network consisting of a voltage-controlled oscillator, a phase comparator, low-pass filter, and an amplifier. The PLL can be used as an FM detector of extreme linearity, as a tunable filter, and as an extremely stable oscillator. When combined with an external reference oscillator it will function as a frequency synthesizer, yielding stable outputs at various frequencies. 6. A voltage-controlled oscillator and a comparator feeding back a control signal forcing the oscillator to lock onto an input signal. 7. A circuit containing a voltage-controlled oscillator whose output phase or frequency can be steered to keep it in sync with a reference source. A PLL circuit is generally used to lock onto and “up-convert” the frequency of a stable source. 8. A circuit for synchronizing a variable local oscillator with the phase of a transmitted signal.

Phase-locked loop, 2.

Phase-locked loop, 3.

phase magnet—Also called trip magnet. A magnetically operated latch used to phase a facsimile transmitter or recorder.

phase margin—1. A safety factor in phase shift. When the loop gain is 1.0 or more and the phase shifts total 180°, instability will occur. The amount that the total phase shift is less than 180° is called the phase margin.

2. The additional amount of phase shift of the output signals in an operational amplifier at the open-loop unity-gain crossover frequency that would produce instability.

phase meter—Also called phase-angle meter. An instrument for measuring the difference in phase between two alternating quantities of the same frequency.

phase modifier—A device that supplies leading or lagging voltamperes to the system to which it is connected.

phase-modulated transmitter—A transmitter whose output is a phase-modulated wave.

phase-modulated wave—A wave whose phase angle has been caused to deviate from its original (no-signal) angle by an amount proportional to the modulating signal amplitude.

phase modulation—Abbreviated pm. 1. Modulation in which the angle of a sine-wave carrier deviates from the original (no-signal) angle by an amount proportional to the instantaneous value of the modulating wave. Phase and frequency modulation in combination are commonly referred to as frequency modulation. 2. Method of modulation in which the amplitude of the modulated wave remains constant, while varying in phase with the amplitude of the modulating signal. A phase-modulated wave is electrically identical to a modified frequency-modulated wave and vice versa. 3. Variation of the phase of the audio-modulating signal in accordance with the superimposed intelligence. Unlike amplitude modulation, in both phase modulation and frequency modulation the average energies of the modulated signals are the same. 4. Variation of an analog signal's phase in direct relationship to digital input information.

phase modulator—A circuit that modulates the phase of a carrier signal.

phase multiplexing—The process of encoding two (or more) information channels on a single tone.

phase multiplier—A device that multiplies the frequency of signals used for phase comparison so that phase differences may be measured to a higher degree of resolution.

phase noise—A measure of the random phase instability of a signal.

phase offset—The difference between voltage and current in an ac power line with a lagging or leading power factor.

phase-propagation ratio—In wave propagation, the propagation ratio divided by its magnitude. Expressed as a unit vector of the same angle as the propagation ratio.

phaser—1. A device for adjusting facsimile equipment so that the recorded area bears the same relationship to the record sheet as the corresponding transmitted area of the scanning line. 2. A microwave ferrite phase shifter that employs a longitudinal magnetic field along a rod or rods of ferrite in a waveguide.

phase-recovery time (t_r and pre- t_r tubes)—The time required for a fired tube to deionize to such a level that a specified phase shift is produced in the low-level radio-frequency signal transmitted through the tube.

phase resonance—Also called velocity resonance. Resonance in which the angular phase difference between the fundamental components of the oscillation or vibration and the applied agency is 90° .

phase-response characteristic—The phase displacement versus frequency properties of a network or system.

phase reversal—A 180° change in phase (or one half cycle) such as a wave might undergo upon reflection under certain conditions.

phase-reversal protection—In a polyphase circuit, the interruption of power whenever the phase sequence of the circuit is reversed.

phase meter — phase-shift discriminator

phase-reversal switch—A switch used on a stereo amplifier or in a speaker system to shift the phase 180° on one channel.

phase-rotation relay—See phase-sequence relay.

phase-sensitive amplifier—A servoamplifier whose output signal polarity or phase is dependent upon the polarity or phase relationship between an error (input) voltage and a reference voltage.

phase-sensitive detector—A system that produces a dc output signal in response to an ac input signal of a defined frequency equal to the frequency of ac reference signal. The dc output is proportional to both the amplitude of the ac input signal and the cosine of its phase angle relative to that of the reference signal. Used as synchronous rectifiers in chopper dc amplifiers and for the accurate measurement of small ac signals obscured by noise.

Phase-sensitive detector.

phase-sequence indicator—A device that indicates the sequence in which the fundamental components of a polyphase set of potential differences or currents successively reach some particular value (e.g., their maximum positive value).

phase-sequence relay—Also called phase-rotation relay. A relay that functions according to the order in which the phase voltages successively reach their maximum positive values.

phase-sequence voltage relay—A device that functions upon a predetermined value of polyphase voltage in the desired phase sequence.

phase shift—1. The difference between corresponding points on input and output signal waveshapes (not affected by a magnitude) expressed as degrees lead or lag. 2. A change in the phase of a periodic quantity. 3. The changing of phase of a signal as it passes through a filter. A delay in time of the signal is referred to as phase lag; in normal networks, phase lag increases with frequency, producing a positive envelope delay. It is possible for an output signal to experience a time shift ahead of the input signal, which is called phase lead. The phase shift is always dependent on frequency.

phase-shift circuit—A network that shifts the phase of one voltage with respect to another voltage of the same frequency.

phase-shift discriminator—A circuit that produces an output proportional to the phase difference

between two input signals. When used as an FM demodulator, the input is a set of push-pull signals and a reference voltage 90° displaced from each of them. These are taken across tuned circuits in such a way that the phase difference between the push-pull signals and the reference is very nearly proportional to the difference between the input frequency and the resonant frequency of the tuned circuits.

phase shifter — A device in which the output voltage (or current) may be adjusted to have some desired phase relationship with the input voltage (or current).

phase-shifting transformer — Also called a phasing transformer. A transformer connected across the phases of a polyphase circuit to provide voltages of the proper phase for energizing varimeters, varhour meters, or other instruments. *See also* rotatable phase-adjusting transformer.

phase-shift keying — 1. A form of phase modulation in which the modulating function shifts the instantaneous phase of the modulation wave between predetermined discrete values. 2. The encoding of digital information as different phases of signal elements having constant amplitude and frequency.

phase-shift microphone — A microphone whose directional properties are provided by phase-shift networks.

phase-shift oscillator — An oscillator in which a network having a phase shift of an odd multiple of 180° (per stage) at the oscillation frequency is connected between the output and input of an amplifier. When the phase shift is obtained by resistance-capacitance elements, the circuit is called an *RC* phase-shift oscillator.

Phase-shift oscillator.

phase simulator — A precision test instrument that generates reference and data signals on the same frequency but precisely separated in phase. It is normally used to check out the precision phase meters.

phase splitter — 1. A device that produces, from a single input wave, two or more output waves that differ in phase from one another. 2. In color television, the stage that takes I and Q signals from demodulators, produces four signals — positive and negative I and Q — and feeds them to the matrix. 3. A circuit that generates out of an ac input signal two equal-amplitude outputs, one of which is 180° out of phase with the other; i.e., one is the other inverted. The dc levels may not be identical.

phase-tuned tube (tr tubes) — A fixed tuned broadband tr tube in which the phase angle through it and the reflection it introduces are kept within limits.

phase undervoltage relay — A relay that is tripped by the reduction of one phase voltage in a polyphase circuit.

phase velocity — 1. The velocity at which a point of constant phase is propagated in a progressive sinusoidal

wave. 2. The velocity with which a point where there exists an electromagnetic wave of a certain fixed phase moves through space in the direction of propagation of the wave.

phase-versus-frequency response characteristic — A graph or other tabulation of the phase shift occurring, in an electrical transducer, at several frequencies within a band.

phasing — 1. Causing two systems or circuits to operate in phase or at some desired difference from the in-phase condition. 2. Adjusting a facsimile-picture position along the scanning line. 3. In stereo application, the establishment of the correct relative polarity in the connection between amplifier output and speakers so that one speaker tends to reinforce rather than cancel the output of the other (particularly evident at low frequencies).

phasing capacitor — A capacitor used in a crystal-filter circuit for neutralizing the capacitance of the crystal holder.

phasing line — In facsimile, the portion of the scanning line set aside for the phasing signal.

phasing pulse — A short pulse or signal employed for phasing the recorder with the transmitter in a television or facsimile system.

phasing signal — In facsimile, a signal used for adjusting the position of the picture along the scanning line.

phasing transformer — *See* phase-shifting transformer.

phasitron — A tube designed to produce a frequency-modulated audio signal, which is induced by a varying field from a magnet placed around the glass envelope of the tube.

phasmajector — *See* monoscope.

phasor — An entity that includes the concepts of magnitude and direction in a reference plane.

pH electrode — Transducer sensitive to hydrogen ion concentration. The sensor comprises a thin-walled glass membrane (glass electrode) or spongy platinum exposed to gaseous hydrogen (hydrogen electrode) or platinum exposed to quinhydrone (quinhydrone electrode), all of which develop an electric force proportional to the hydrogen-ion concentration of a solution when immersed in the solution.

phenolic material — Any one of several thermosetting plastic materials available that may be compounded with fillers and reinforcing agents to provide a broad range of physical, electrical, chemical, and molding properties.

phi polarization — In an electromagnetic wave, the state in which the *E* vector of the wave is tangential to the lines of latitude of some given spherical frame of reference.

pH meter — An instrument used with a probe to determine the alkalinity or acidity of a solution.

phon — The subjective unit for measuring the apparent loudness level of a sound. Numerically equal to the sound-pressure level, in decibels relative to 0.0002 microbar, of a 1000-hertz tone that is considered by listeners to be equivalent in loudness to the sound under consideration.

phone — 1. A telephone. 2. An earphone. 3. A headphone.

phone jack — Also called telephone jack. 1. A jack designed for use with phone plugs. 2. Receptacle having two or more through circuits. May also have shunt circuits and/or isolated switching circuits. Used for extending circuits through mating plugs. Phone jacks are short or long types, depending on physical dimensions.

phonemes — 1. The minimal set of shortest segments of speech that, if substituted one for another, convert one

Phone jack.

word to another. Phonemes are the elements on which computer speech are based. 2. A class of speech sounds that are alike, except as they are modified by the sound of adjacent letters. 3. A set of abstract units that can be used for writing a language in a systematic and unambiguous way. English has about 40 phonemes: 16 vowel phonemes and 24 consonant phonemes.

phone phreak — 1. A person involved in exploring a telephone or computer network by routing calls manually. 2. One who makes telephone calls without paying for them.

phone plug — Also called telephone plug. A plug used with headphones, microphones, and other audio equipment. It is a male connecting device (almost always connected to a cable) that connects with a phone jack. Consists usually of finger and handle that comprise the through circuit, terminals, insulators, and handle. A cable clamp may or may not be part of a phone plug design.

Phone plug.

phonetic alphabet — A list of standard words, one for each letter in the alphabet. It is used for distinguishing the letters in a spoken radio or telephone message. The list is as follows:

Alfa	November
Bravo	Oscar
Charlie	Papa
Delta	Quebec
Echo	Romeo
Foxtrot	Sierra
Golf	Tango
Hotel	Uniform
India	Victor
Juliet	Whiskey
Kilo	X-ray
Lima	Yankee
Mike	Zulu

phonocardiogram — A graphic recording of the sounds produced by the heart and its associated parts (e.g., its mitral or aortic valves).

phonocardiograph — An instrument for recording sounds of the heart on a strip chart.

phonocardiography — The recording and interpretation of the sounds of the heart. A typical instrument for this purpose consists of a microphone, an amplifier, a cathode-ray tube or strip-chart recorder, and sometimes a speaker or headset.

phono cartridge — The means by which stylus movements are converted into an electrical signal. Various

phone phreak — phosphor

versions of magnetic (moving iron, magnet, or coil), ceramic-crystal, capacitive (electret), and strain-gauge devices are in use.

phonocatheter — A catheter-microphone combination that is inserted through the artery into the heart. It picks up inner cardiac sounds.

phonoelectrocardioscope — A dual-beam oscilloscope that displays both ECG signals and heart-sound signals.

phonograph — An instrument for reproducing sound. It consists of a turntable on which the grooved medium containing the impressed sound is placed, a needle that rides in the groove, and an electrical (formerly mechanical) amplifying system for taking the minute vibrations of the needle and converting them into electrical (formerly mechanical) impulses that drive a speaker.

phonograph oscillator — An rf oscillator circuit whose output is modulated by a phonograph pickup and sent through space to a receiver. Thus, no wires to the receiver are needed.

phonograph pickup — Also called mechanical reproducer, pickup, or phono pickup. A mechanoelectric transducer that is actuated by modulations present in the groove of a recording medium and that transforms this mechanical input into an electrical output.

phono jack — A jack designed to accept a phono plug. Receptacle having two through circuits (coaxial oriented) primarily intended for connecting audio signals between phonograph and amplifiers. Now widely used for many other types of signal, including occasionally rf.

phonon — 1. A lattice vibration with which a discrete amount (quantum) of energy is associated. Some thermal and electrical properties of the lattice are theoretically treated in terms of electro-phonon interactions. 2. Quantum of thermal energy used to help calculate the thermal vibration of a crystal lattice. 3. Sharply tuned radiation of superhigh-frequency sound waves.

phonons — Packets of sound energy vibrating in a solid at ultrahigh frequencies — so high that the energy is commonly thought of as heat.

phono pickup — See phonograph pickup.

phono plug — A plug used at the end of a shielded conductor for feeding audio-frequency signals to a mating phono jack on an audio preamplifier or amplifier.

Phono plug.

phonoselectroscope — A stethoscopic device that suppresses low frequencies (characteristic of the normal heart function) to permit detection of higher-frequency sounds.

phosphor — 1. A layer of luminescent material applied to the inner face of a cathode-ray tube. During bombardment by electrons it fluoresces, and after the bombardment, it phosphoresces. 2. A material that emits light when excited (energized) by radiant energy. 3. Generic name for the class of substances deposited on the inner surface of television tubes and other cathode-ray tubes that exhibit luminescence when stimulated by an electron beam. 4. The compound, typically polycrystalline, that produces photons upon stimulation — for instance, by high-energy electrons or high electrostatic fields.

phosphor bronze—A frequently used and easily formed connector contact material, with good corrosion resistance and fair conductivity.

phosphor-dot faceplate—1. The glass viewing screen on which the trios of color phosphor dots are mounted in a three-gun picture tube. 2. A glass plate in a tricolor picture tube. May be the front face of the tube or a separate internal plate. In either case, its rear surface is covered with an orderly array of tricolor lines or tricolor phosphor dots. When excited by electron beams in proper sequence, the phosphors glow in red, green, and blue to produce a full-color picture.

phosphor dots—Minute particles of phosphor on the viewing screen of a picture tube. On a tricolor picture tube, the red, green, and blue phosphor dots are placed on the viewing screen in a pattern of dot triads—a phosphor dot of each color forming one-third of the triad.

Phosphor dots.

phosphorescence—1. The emission of light from a substance for a long period after excitation has been removed. Essentially, it is time of persistence that distinguishes phosphorescence from fluorescence. For example, the hands of clocks coated in radium salts glow after exposure to ordinary light. *See also* afterglow. 2. The emission of light from a source that is delayed by over 10^{-8} seconds following excitation. 3. Luminescence of a material that occurs while, and for some time after, the material has been stimulated by radiation energy. *See also* luminescence.

phosphorescence spectroscopy—The spectroscopic study of the radiation emitted in the lifetime of phosphorescence.

phosphors—Chemical substances that exhibit fluorescence when excited by ultraviolet radiation, X-rays, or an electron beam. The amount of visible light is proportional to the amount of excitation energy. If fluorescence decays slowly after the exciting source is removed, the substance is said to be phosphorescent.

phosphor trio—In the phosphor screen of a tricolor kinescope, closely spaced triangular groups of three phosphor dots accurately deposited in interlaced positions.

phot—Abbreviated pt. The unit of illumination when the centimeter is taken as the unit of length; it is equal to 1 lumen per square centimeter.

photoacoustic effect—Generation of an acoustical signal by a sample exposed to modulated light.

photobiology—The study of the effects on living matter (or substances derived therefrom) of electromagnetic radiation extending from the ultraviolet through the visible light spectrum into the infrared. The conversion of electromagnetic energy into chemical energy. Photosynthesis is an important branch of photobiological investigation.

photocathode—1. An electrode that releases electrons when exposed to light or other suitable radiation. Used in phototubes, television camera tubes, and other light-sensitive devices. 2. An electrode used to release photoelectric emission when irradiated, making it then the irradiated negative electrode of a phototube. 3. An electrode used for obtaining photoelectric emission.

photocathode luminous sensitivity—The responsiveness of a photocathode to luminous energy; equal to the ratio of the photoelectric emission to the incident luminous flux. The measurement is made under specified conditions of illumination, usually with radiation from a tungsten-filament lamp operated at a color temperature of 2870 K. The cathode is usually illuminated by a collimated beam at normal incidence.

photocathode radiant sensitivity—The ratio of the photoelectric emission current from the photocathode to the incident radiant flux. It is usually measured at a given wavelength under specified conditions of irradiation with a collimated beam at normal incidence.

photocathode tube response—The photoemission current resulting from a specified luminous flux from a tungsten lamp filament at a color temperature of 2870 K when the flux is filtered by a specified blue filter.

photocell—*See* photoelectric cell.

photochemical radiation—Energy in the ultraviolet, visible, and infrared regions used to produce chemical changes in materials.

photochromic—Pertaining to a single-crystal inorganic material used as a display and storage element. The material can be from one of several families of materials, such as fluorides or titanates. The display color and storage time are determined by the amount and kind of doping of the material.

photoconduction—An increase in the electrical conduction capability resulting from the absorption of electromagnetic radiation by the material.

photoconductive cell—Also called photoresistive cell and photoresistor. 1. A photoelectric cell whose electrical resistance varies inversely with the intensity of light that strikes its active material. 2. A device for detecting or measuring electromagnetic radiation intensity by variation of the conductivity of a substance caused by absorption of the radiation. 3. Photosensor normally made of cadmium sulfide (CdS) or cadmium selenide (CdSe). Unlike the junction types, it has no junction. The entire layer of material changes in resistance

Photoconductive cell.

when it is illuminated (analogous to a thermistor except the heat is replaced by light). 4. *See* photoconductive detector.

photoconductive detector—A detector used in the spectral region from the optical to the far infrared. It is based on photoconductive effects in semiconductors that are sensitive to photons from light to lower energies of microwave quanta. *See* intrinsic photoconductivity; extrinsic photoconductivity.

photoconductive device—A device that makes use of photoconductivity, such as a photoconductive cell.

photoconductive effect—1. The change of electrical conductivity of a material when exposed to varying amounts of radiation. 2. The phenomenon in which some nonmetallic materials exhibit a marked increase in electrical conductivity on absorption of photon energy. Photoconductive materials include gases (ionization) as well as crystals. They are used in conjunction with semiconductor materials that are ordinarily poor conductors but become distinctly conducting when subjected to photon absorption. The photons excite electrons into the conduction band, where they move freely, resulting in good electrical conductivity. The conductivity increase is due to the additional free carriers generated when photon energies are absorbed in energy transitions. The rate at which free carriers are generated and the length of time they persist in conducting states (their lifetime) determine the amount of conductivity change. 3. The alteration of electric conductivity produced by the absorption of varying amounts of radiation composed of photons.

photoconductive film—A film of material whose electrical current-carrying ability is enhanced when illuminated by electromagnetic radiation, particularly in the visible region of the frequency spectrum.

photoconductive gain factor—The ratio of the number of electrons per second flowing through a circuit containing a cube of semiconducting material, whose sides are of unit length, to the number of photons per second of incident electromagnetic radiation absorbed in this volume.

photoconductive material—Material having a high resistance in the dark, and a low resistance when exposed to the light.

photoconductive meter—An exposure meter in which a battery supplies power through a photoconductive cell to an electrical current-measuring device, such as a millimeter, to measure the intensity of radiation, such as light intensity, incident on its active surface.

photoconductive photodetector—A photodetector that makes use of the phenomenon of photoconductivity in its operation. Thus, it detects the presence of electromagnetic radiation, particularly in the visible region of the frequency spectrum, by changing its electrical resistance in accordance with the intensity of the incident radiation, thus controlling the current from an applied bias voltage power source. Usually a source of voltage is needed to drive a current that will vary according to the variation in conductivity resulting from the variation in incident electromagnetic radiation.

photoconductivity—1. The greater electrical conductivity shown by some solids when illuminated. The incoming radiation transfers energy to an electron, which then takes on a new energy level (in the conduction band) and contributes to the electrical conductivity. 2. The ability of a material to hold a charge of electricity (insulator) in the absence of light yet act as a conductor of electricity when exposed to light. 3. The increase in electrical conductivity displayed by many materials, particularly

nonmetallic solids, when they absorb electromagnetic radiation. 4. Characteristic of a material that produces changes in the electrical conductivity of the material as a result of absorption of photons.

photoconductor—1. A passive, high-impedance device composed of thin single-crystal or polycrystalline films of compound semiconductor materials. When the sensitive surface is illuminated, its resistance decreases and, hence, its conductivity increases. 2. A light-sensitive resistor whose resistance decreases with increases in light intensity, when illuminated. Consists of a thin single crystal or polycrystalline films of compound semiconductor substances. 3. A device whose electrical resistance varies in relationship with exposure to light. 4. A material, usually a nonmetallic solid, whose conductivity increases when it is exposed to electromagnetic radiation. 5. A metallic substance, such as selenium or cadmium sulfide, that is capable of conducting and retaining electrical charges. If any portion of a photoconductor is exposed to light, that part will lose its charge. Photoconductive materials are employed in the electrostatic process to retain a latent image (charge) of a document, which is subsequently imbued with toner particles to create an image.

photocoupled solid-state relay—A relay in which the control signal activates the load circuit via a light source and photosensitive semiconductors; electrical isolation between input and output is complete.

photocurrent—1. The difference between light current and dark current in a photodetector. 2. *See* photoelectric current.

photo-Darlington—A light-sensitive Darlington-connected transistor pair. The photo-Darlington has a very high sensitivity to illumination or radiation.

Photo-Darlington symbol.

photodetector—1. A device that senses incident illumination. 2. Any device that utilizes the photoelectric effect to detect the presence of light. 3. A device that provides an electrical output signal when subjected to radiation in the visible, infrared, or ultraviolet regions of the electromagnetic spectrum. Photodetectors are square-law detectors that respond to the intensity of light averaged over some time period. Photodiodes, phototransistors, and photo-Darlingtons are the most common types of photodetectors. 4. A device capable of extracting the information from an optical carrier, i.e., a thermal detector or a photon detector, the latter being used for communications more than the former. *See* photoconductive photodetector; photoelectromagnetic photodetector; photoemissive photodetector; photovoltaic photodetector.

photodetector responsivity—The ratio of the rms value of the output current or voltage of a photodetector to the rms value of the incident optical power input. Note: In most cases, detectors are linear in the sense that the responsivity is independent of the intensity of the incident radiation. Thus, the detector response in amperes

or volts is proportional to incident optical power, watts. Differential responsivity applies to small variations in optical power.

photodielectric effect—The effect, present in particular phosphors, that is defined as a transformation in the dielectric constant and of a material when illuminated. The effect is observed only in phosphors that show photoconductivity during luminescence.

photodiffusion effect—1. See Dember effect. 2. The potential difference between two areas of a semiconductor when one is exposed to light.

photodiode—1. A pn semiconductor diode designed so that light falling on it greatly increases the reverse leakage current, so that the device can switch and regulate electric current in response to varying intensity of light. 2. A fiber optics receiver that changes light signals back to electrical signals. 3. A two-electrode radiation-sensitive junction formed in a semiconductor material in which the reverse current varies with illumination. 4. A junction diode that is responsive to radiant energy. Photodiodes have a high degree of linearity between the input radiation and the output current. The resistance across the semiconductor junction changes as a function of the light falling on it. Photodiodes are very fast in response, but limited in sensitivity due to the small area of the junction. They have faster switching speeds than phototransistors.

Symbol.

Operation.

Photodiode.

photodiode sensor array scanner—A type of scanner that employs a stationary configuration of tiny photodiodes arranged in a matrix that equals in width one lateral scan line of a document. An original is roller fed from a flatbed tray and passes by the sensor array one line at a time. Light is reflected from each line and focused through a lens onto the face of the photodiode array. Each diode acts as an independent photosensor in converting a small picture element into part of the total electrical signal for a scan line.

photodischarge spectroscopy—Abbreviated PDS. A spectroscopic process that detects and analyzes the discharge from an extrinsic surface with less than band-gap light. This method may determine the

extrinsic surface-state energy levels of a semiconductor surface.

photoelasticity—Changes in the optical properties of transparent isotropic dielectrics subject to stress.

photoelectric—Pertaining to the electrical effects of light or other radiation—i.e., emission of electrons, generation of a voltage, or a change in electrical resistance upon exposure to light.

photoelectric absorption—Conversion of radiant energy into photoelectric emission.

photoelectric alarm system—An alarm system that employs a light beam and photoelectric sensor to provide a line of protection. Any interruption of the beam by an intruder is sensed by the sensor. Mirrors may be used to change the direction of the beam. The maximum beam length is limited by many factors, some of which are the light source intensity, number of mirror reflections, detector sensitivity, beam divergence, fog, and haze.

photoelectric beam-type smoke detector—A smoke detector that has a light source which projects a light beam across the area to be protected onto a photoelectric cell. Smoke between the light source and the receiving cell reduces the light reaching the cell, causing actuation.

photoelectric cathode—A cathode whose primary function is photoelectric emission.

photoelectric cell—Also called photocell. 1. A cell, such as a photovoltaic or photoconductive cell, whose electrical properties are affected by illumination. The term should not be used for a phototube, which is a vacuum tube and not a cell. 2. A resistive, bulk-effect type of photosensor. Used when it is desirable to wire several photoreceivers in series or in parallel.

photoelectric colorimeter—A colorimeter that uses a photoelectric cell and a set of color filters to determine, by the output current for each filter, the chromaticity coordinates of light of a given sample.

photoelectric conductivity—The increased conductivity exhibited by certain crystals when struck by light (e.g., a selenium cell).

photoelectric constant—A quantity that, when multiplied by the frequency of the radiation causing the emission of photoelectrons, gives (in centimeter-gram-second units) the voltage absorbed by the escaping photoelectron. The constant is equal to h/e , where h is Planck's constant and e is the electron's charge.

photoelectric control—1. The control of a circuit or piece of equipment in response to a change in incident light impinging on a photosensitive device. 2. The control of an instrument or electrical circuit by the current produced by varying radiation incident to a photoelectric cell.

Photoelectric control.

photoelectric counter—A device that registers a count whenever an object breaks the light beam shining on its phototube or photocell. An amplifier then boosts the minute energy to register on a mechanical or other type of counter. Slow counting rates can be recorded by a mechanical counter, but high rates require an electronic counter.

photoelectric current—The stream of electrons emitted by a phototube when the cathode is exposed to light.

photoelectric cutoff control—A photorelay circuit used in machines for cutting long strips of paper, cloth, metal, or other material accurately into predetermined lengths or at predetermined positions.

photoelectric effect—1. The transfer of energy from incident radiation to electrons in a substance. This phenomenon includes photoelectric emission of electrons from the surface of a metal, the photovoltaic effect, and photoconductivity. 2. Interaction between radiation and matter resulting in the absorption of photons and the consequent generation of mobile charge carriers. 3. The changes in material electrical characteristics due to photon absorption. 4. The emission of electrons as the result of the absorption of photons in a material. This effect is the means by which photons may be detected. (The photons can be of any energy, and the electrons can be released into a vacuum or into a second material. The material itself may be solid, liquid, or gas. Thus, photoelectromagnetic effects are photoelectric effects.)

photoelectric electron-multiplier tube—A vacuum phototube that employs secondary emissions to amplify the electron stream emitted from the illuminated photocathode.

photoelectric emission—1. Electron emission due directly to the incidence of radiant energy on the emitter. 2. The phenomenon of emission of electrons by certain materials on exposure to radiation in and near the visible region of the spectrum.

photoelectric exposure meter—A device consisting of a microammeter, a photovoltaic cell, and a battery. Used for the measurement of scene brightness and the determination of correct exposure for photographic processes.

photoelectric flame-failure detector—An industrial electronic control employing a phototube and amplifier to actuate an electromagnetic or other valve that cuts off the fuel flow when the fuel-consuming flame is extinguished and light no longer falls on the phototube.

photoelectric inspection—Quality control of a product by means of a phototube, light-beam system, and associated electronic equipment.

photoelectric intrusion detector—A burglar-alarm system in which interruption of a light beam by an intruder reduces the illumination on a phototube, phototransistor, or photocell and thereby closes an alarm circuit.

photoelectric liquid-level indicator—A level indicator in which the rising liquid interrupts the beam of light in a photoelectric control system.

photoelectric material—Any material that will emit electrons when illuminated in a vacuum (e.g., barium, cesium, lithium, potassium, rubidium, sodium, and strontium).

photoelectric multiplier—A phototube in which the primary photoemission current, prior to being extracted at the anode, is multiplied many times.

photoelectric phonograph pickup—A phonograph reproducing device consisting essentially of a light source, a jewel stylus to which a very thin mirror is attached, and a selenium cell that picks up light reflected from the mirror. Sidewise movements of the stylus in the

record groove cause the amount of reflected light to vary, and accordingly the resistance of the selenium cell. The light source is fed by a radio-frequency oscillator rather than from the power line, to eliminate hum caused by a 60-hertz flicker from the light beam.

photoelectric photometer—Also known as electronic photometer. A photometer with a photocell, phototransistor, or phototube for measuring the intensity of light. *See also* electronic photometer.

photoelectric photometry—The use of photoelectric sensors to detect and measure the intensity of a light source. This application, as compared with human observation, results in higher speeds of operation, a greater consistency of results, and superior accuracy in certain photometric situations.

photoelectric pickup—A transducer that transforms a change in light into an electric signal.

photoelectric pyrometer—1. An instrument for measuring high temperatures from the intensity of the light given off by the heated object. 2. An instrument used to measure the temperature of a source through the use of photoelectric cells to detect and measure the intensity of the light emitted by the source.

photoelectric reader—A device that reads information stored in the form of holes punched in paper tape or cards, by sensing light passed through the holes.

photoelectric receiver—An instrument that uses a photocell to detect and measure the intensity of incident light.

photoelectric recorder—An optical recording instrument employing a light source and phototube for the basic measuring element.

photoelectric reflectometer—A photoelectric photometer used to measure the reflectance of a surface.

photoelectric register control—A photoelectric device used for controlling the position of a strip of paper, cloth, metal, etc., with respect to the machine through which it is being passed.

photoelectric relay—Also called light relay. 1. A relay combined with a phototube (and amplifier, if necessary), so arranged that changes in incident light on the phototube cause the relay contacts to open or close. 2. A relay that opens or closes an electrical circuit depending on the intensity of the light incident to a photoelectric device connected to the relay.

photoelectric scanner—A light source, lens system, and one or more phototubes in a single, compact housing. It is mounted a few inches above a moving surface, where it actuates control equipment when the amount of light reflected from the surface changes.

photoelectric sensitivity—Also called photoelectric yield. 1. The rate at which electrons are emitted from a metal per unit radiant flux at a given frequency. 2. That property of a material that determines its ability to release electrons when absorbing photons.

photoelectric sensor—A device that detects a visible or invisible beam of light and responds to its complete or nearly complete interruption. *See also* modulated photoelectric alarm system; photoelectric alarm system.

photoelectric smoke detector—A photoelectric instrument used to measure the density of smoke and to sound an alarm when a predetermined smoke density is exceeded.

photoelectric sorter—An industrial-electronic control employing a light beam, phototube, and amplifier to sort objects according to color, size, shape, or other characteristics.

photoelectric spectrophotometer—A system consisting of a spectrophotometer with a photoelectric detector for measurement of radiant energy.

photoelectric spot-type smoke detector—A smoke detector that contains a chamber with covers that prevent the entrance of light but allow the entrance of smoke. The chamber contains a light source and a photosensitive cell so placed that light is blocked from it. When smoke enters, the smoke particles scatter and reflect the light into the photosensitive cell, causing an alarm.

photoelectric threshold—The quantum energy just sufficient to release photoelectrons from a given surface. The corresponding frequency is the critical, or threshold, frequency.

photoelectric timer—An electronic instrument that automatically turns off an X-ray machine or other photographic device when the film reaches the correct exposure.

photoelectric transducer—A transducer that converts changes in light energy into electrical changes.

photoelectric tube—*See* phototube.

photoelectric work function—The energy required to transfer electrons from a given metal to a vacuum or other adjacent medium during photoelectric emission. It is sometimes expressed as energy in ergs or joules per unit of emitted charge, and sometimes as energy per electron in electron volts.

photoelectric yield—*See* photoelectric sensitivity.

photoelectromagnetic effect—Also called photomagnetolectric effect. 1. The production of a potential difference by virtue of the interaction of a magnetic field with a photoconductive material that is subjected to incident radiation. (The incident radiation creates hole-electron pairs that diffuse into the material. The magnetic field causes the pair components to separate, resulting in a potential difference across the material. In most applications the light is made to fall on a flat surface of an intermetallic semiconductor located in a magnetic field that is parallel to the surface, excess hole-electron pairs are created, and these carriers diffuse in the direction of the light but are deflected by the magnetic field to give a current through the semiconductor that is at right angles to both the light rays and the magnetic field. This is due to transverse forces acting on electrons and holes diffusing into the semiconductor from the surface.) 2. Interaction of a magnetic field with a photoconductive substance exposed to light waves to create a potential difference. 3. *See* Dember effect.

photoelectromagnetic photodetector—A photodetector that makes use of the photoelectromagnetic effect; namely, it uses an applied magnetic field.

photoelectromotive force—1. Electromotive force caused by photovoltaic action. 2. The force that stimulates the emission of an electric current when photovoltaic action creates a potential difference between two points.

photoelectrons—1. The electrons emitted from a metal in the photoelectric effect. 2. The electrons released in photoelectric activity.

photoemission—*See* photoelectric emission.

photoemissive—Capable of emitting electrons when under the influence of light or other radiant energy.

photoemissive cell—1. A device that detects or measures radiant energy by measurement of the resulting emission of electrons from a surface that has or displays a photoemissive effect. 2. *See also* photoemissive detector.

photoemissive detector—1. An electron tube in which the anode current varies with the intensity of light incident on the cathode. 2. A photosensor that measures light by the emission in a vacuum of one electron per photon impinging on a metal photocathode.

photoemissive effect—The emission of electrons as a result of incident radiation.

photoemissive photodetector—A photodetector that makes use of the photoemissive effect. Usually an applied electric field is necessary to attract or collect the emitted electrons.

photoemissive tube photometer—A photometer that uses a tube made of a photoemissive material. It is highly accurate, requires electronic amplification, and is used mainly in laboratories.

photoemissivity—The property of a substance that causes it to emit electrons when electromagnetic radiation in the visible region of the frequency spectrum is incident on it. Normally an electric field is applied to collect the emitted electrons.

photofabrication—The production of precise shapes in metal or other substances by recording a precise photographic image on the surface of the substance and etching away the unprotected areas by chemical or electrical means.

photoflash—A means of firing expendable flash-bulbs with an instantaneous surge of current supplied by two or more 1.5-volt single-cell batteries, or by the discharge of a capacitor that has been charged to full capacity by a medium-voltage battery.

photoflash bulb—1. An oxygen-filled glass bulb containing a metal foil or wire. A surge of current heats the metal to incandescence, and a brilliant flash of light is produced when the wire burns in the oxygen. 2. A glass bulb packed with a highly inflammable mixture of zirconium, wool, and glass. The mixture is ignited and produces an instantaneous flash when a small powder-filled primer cap in the base of the bulb is set off by a small hammer.

photoflash tube—*See* flash tube.

photoflood lamp—An incandescent lamp employing excess voltage to give brilliant illumination. Used in television and photography, it has a life of only a few hours.

photogalvanic cell—A cell that generates an electromotive force when light falls on either of the electrodes immersed in an electrolyte.

photogalvanometer—An instrument for recording the electric variations produced by emotional stresses.

photogenerator—A semiconductor-junction device that emits light when pulsed.

photoglow tube—A gas-filled phototube used as a relay. This is done by making the operating voltage so high that ionization and a glow discharge occur, accompanied by considerable current, when a certain illumination is reached.

photographic writing speed—A figure of merit used to describe the ability of a particular combination of camera, film, oscilloscope, and phosphor to record a high-speed trace. It expresses the maximum single-event spot velocity (usually in centimeters per microsecond) that can be recorded on film as an image just discernible to the eye.

photoionization—Ionization occurring in a gas as a result of visible light or ultraviolet radiation.

photoisland grid—A photosensitive surface in the storage-type Farnsworth dissector tube used with television cameras. It comprises a thin, finely perforated (about 400 holes per square inch or 62 per square centimeter) sheet of metal. (No longer used in current equipment.)

photojunction battery—A nuclear-type battery in which the radioactive material, promethium 147, irradiates a phosphor that converts nuclear energy into light. The light is then converted to electrical energy by a small silicon junction.

photolithography—1. The process whereby patterns are etched into an oxide or similarly passive layer

coating a semiconductor crystal wafer, using a photoresist process followed by an etchant. The remaining oxide material thus forms a precisely located miniature mask, used to control impurity doping and contact metallization. 2. The process used to print the masks on the wafer. It involves a photosensitive emulsion and selective etching analogous to commercial lithography.

photoluminescence—Luminescence stimulated by visible light or ultraviolet radiation. A special case of electroluminescence that involves a light-to-light conversion, the emitted light differing from the stimulating radiation in frequency.

photomagnetic effect—The direct effect of light on the magnetic susceptibility of certain substances.

photomagnetolectric effect—1. The production in a semiconductor of an electromotive force normal to both an applied magnetic field and to a photon flux of proper wavelength. 2. *See* photoelectromagnetic effect.

photomask—1. A photographic template through which images are transferred by light onto a photoresist coating. 2. A transparent plate slightly larger than a silicon slice, containing numerous tiny opaque spots, used in the planar diffusion process as a shadow mask over a slice coated with photoresist to expose the surface of the slice to acid in desired spots in a later step. 3. A square, flat, glass substrate, coated with a photographic emulsion or a very thin layer of metal, on which appear several hundred circuit patterns (each containing thousands of images). The patterns are exposed onto semiconductor wafers. 4. A square-shaped glass substrate, coated with either an extremely thin metal layer or a photographic emulsion, on which hundreds of complex circuit patterns have been precisely reproduced. Each circuit pattern contains literally thousands of geometric images, some as small as 50 millionths of an inch (1.27 μm). In much the same way as a photograph is made from a conventional negative in a darkroom, the patterns on the mask are exposed onto a photosensitive wafer surface during each step of the semiconductor wafer processing operation. In projection printing of wafers, the photomasks used are called master plates. In contact printing copies of the master plates, called working plates, are used. As many as 7 to 10 different photomasks typically are required to manufacture a single type of multilayered semiconductor device.

photometer—1. An instrument for measuring the intensity of a light source or the amount of illumination, usually by comparison with a standard light source. 2. A device used to compare the luminous intensities of two sources by comparing the illumination they produce. 3. *See* photoemissive tube photometer.

photometric—Related to measurements of light.

photometric equipment—Photocells of various kinds used to measure photometric quantities, i.e., intensity, luminance, and illuminance. Meter readings are used to express illuminance and, by calibration, to measure intensity and luminance. Other photometric quantities requiring measurement include transmission and reflection densities in photography, the reflectance of a mirror or a screen, and the transmittance of an optical instrument.

photometry—1. The techniques for measuring luminous flux and related quantities (e.g., luminous intensity, illuminance, luminance, luminosity). 2. The science of the measurement of light intensity, where *light* refers to the total integrated range of radiation to which the eye is sensitive. It is distinguished from radiometry, in which each separate wavelength in the electromagnetic spectrum is detected and measured, including the ultraviolet and infrared. 3. The science devoted to the measurement of the effects of electromagnetic radiation on the eye. Photometry is an outgrowth of psychophysical aspects and

involves the determination of visual effectiveness by considering radiated power and the sensitivity of the eye to the frequency in question.

photomultiplier pulse-height resolution—A measure of the smallest change in the number of electrons emitted during a pulse from the photocathode that can be discerned as a change in output-pulse height.

photomultiplier tube—*See* multiplier phototube.

photon—1. A quantum of electromagnetic energy. The equation is $E = h\nu$, where E is the energy, h is Planck's constant and ν is the frequency associated with the photon. The momentum of the photon in the direction of propagation is $h\nu/c$, where c is the velocity of light. 2. A quantum of light; used to help describe characteristics of light in conjunction with the wave theory of light. 3. A quantum of electromagnetic energy carried in a small amount and moving with the speed of light. Optical photons have energies corresponding to wavelengths between 120 and 1800 nanometers. 4. The smallest unit of radiant energy. 5. Particle carrying the energy associated with electromagnetic radiation. 6. An elementary particle of light.

photon-coupled isolator—A circuit-coupling device consisting of an infrared emitter diode coupled to a photon detector over a short shielded light path, which provides extremely high circuit isolation.

photon coupling—Coupling between circuits by a beam of light.

photon detector—A device that responds to incident photons.

photonegative—Having a negative photoconductivity—hence, decreasing in conductivity (increasing in resistance) under the action of light. Selenium sometimes exhibits this property.

photon energy—Planck's constant times photon frequency.

photon flux—Incident photons per second. The product of photon energy and flux is radiant power.

photonics—The technology of generating and harnessing light and other forms of radiant energy, whose unit is the photon. The range of applications of photonics extends from energy generation to detection to communications and information processing.

photo-optic memory—A memory that uses an optical medium for storage. For example, a laser might be used to record on photographic film.

photo-optics—The combination of an input light source and a photoreceiver producing an output signal, assembled either separately or in a single package.

photoparametric diode—A pill-sized device for simultaneously detecting and amplifying optical energy modulated at microwave frequencies.

photophone—A device for converting variations in light intensity into sound.

photoplotter—Device used to generate artwork photographically for printed circuit boards.

photopolymer hologram—A holographic plate coated by photopolymeric mixtures that are composed of one or more monomers and a photoredox catalyst sensitized to visible light. The material becomes a plastic solid when exposed to ultraviolet light and, thus, produces a nonerasable hologram.

photopolymer material—A photosensitive plastic that can be formed optically by photographic methods into three-dimensional configurations to reproduce a planar image precisely and in depth.

photopositive—Having a positive photoconductivity—hence, increasing in conductivity (decreasing in resistance) under the action of light. Selenium ordinarily has this property.

photoradiometer—Instrument for measuring the intensity and penetrating power of radiation.

photoreceiver—A unit consisting of photosensor, focusing lens, and protective enclosure.

photorelay circuit—A form of on-off control actuated by a change of illumination.

photoresist—1. A solution that when exposed to ultraviolet light becomes extremely hard and resistant to etching solutions that dissolve materials such as silicon dioxide. 2. A liquid plastic that hardens into a tough acid-resistant solid when exposed to ultraviolet light. 3. A chemical substance rendered insoluble by exposure to light. By means of a photoresist, a selected pattern can be imaged on a metal. The unexposed areas are washed away and are then ready for etching by acid or doping to make a microcircuit. 4. A material that selectively allows etching of a wafer when photographically exposed. With a negative resist, the resist film under the clear area of a photomask undergoes physical and chemical changes that render it insoluble in a developing solution. In a positive resist, the same areas after exposure are soluble in the developing solution, so they disappear, permitting development of the exposed pattern underneath. 5. A light-sensitive liquid that is spread as a uniform thin film on a wafer or substrate. After baking to solidify the liquid, exposure of specific patterns is performed using a photomask. Material remaining after development shields regions of the wafer from subsequent etch or implant operations.

photoresistive cell—*See* photoconductive cell.

photoresistive or photoconductive transduction—Conversion of the measurand into a change in the resistance of a semiconductor material (by changing the illumination incident on the material).

photoresistor—1. A semiconductor resistor that, when illuminated, drops in resistance. 2. *See* photoconductive cell.

photosensitive—Capable of emitting electrons when struck by light rays.

photosensitive field-effect transistor—A special unipolar field-effect transistor (FET) structure that is positioned on a header to receive illumination transmitted through a lens in the top of the header can. It combines the circuit and device characteristics of a photodiode and a high-impedance low-noise amplifier.

photosensitive recording—Recording by the exposure of a photosensitive surface to a signal-controlled light beam or spot.

photosensitive semiconductor—A semiconductor material in which light energy controls the current-carrier movement.

photosensitivity—That property of materials determining that they react when exposed to light energy.

photosensor—The light-sensitive device in a photoelectric control that converts a light signal into an electric signal.

photosphere—The outermost luminous layer of the gaseous body of the sun.

photoswitch—A solid-state device that functions as a high-speed power switch activated by incident radiation. *See also* LASCR; LASCs.

phototelegraphy—In facsimile, the process of sending photographs over a wire.

photothyristor—A thyristor whose switching action is controlled by light applied to the thyristor gate.

phototransistor—1. A junction transistor with its base exposed to light through a lens in the housing. The collector current increases as the light intensity increases, because of the amplification of the base current by the transistor structure. The device may have only collector and emitter leads, or it may also have a base lead. 2. A

light-sensitive transistor that delivers an electrical output proportional to the light intensity at its input. The low-level photocurrent that is generated is amplified by the current gain of the transistor. The base region (or gate in a FET) may or may not be brought out as an external terminal. 3. Transistor having a base-collector acting as a photodiode. Light generates a base current that turns on the working current through the transistor. This gives a much larger current than a simple photodiode. 4. A transistor whose electrical output current is proportional to the intensity and wavelength of a beam of electromagnetic radiation applied to its input. 5. A solid-state device similar to an ordinary transistor except that incident light on the pn junctions regulates the response of this device. It has built-in gain and a greater sensitivity than that of photodiodes. 6. A type of photosensor, typically used where speed of response is critical or ambient temperature variations are great. 7. A transistor utilizing the photoelectric effect.

With base connection.

Without base connection.

Layering.

Phototransistor.

phototronic cell—1. A type of photovoltaic cell in which a voltage is generated in a layer of selenium during exposure to visible or other radiation. 2. *See* photovoltaic cell.

phototronic photocell—*See* photovoltaic cell.

phototube—Also called photoelectric tube. An electron tube containing a photocathode. Its output depends on the total photoelectric emission from the irradiated area of the photocathode.

phototube bridge circuit—A circuit in which a phototube is one arm of a bridge circuit. With such a circuit, a balanced condition (no signal output) can be reached under either a black-signal or white-signal condition, depending on the impedance adjustments in the other arms.

phototube relay—An electrical relay in which the action of a beam of light on a phototube operates mechanical devices such as counters and safety controls.

phototypesetting—The setting of type via electronic or electromechanical optical systems onto photographic paper or film. Input to such devices can be by direct keyboard entry, paper tape, or magnetic media. Fonts are contained on reduced character matrices through which light is flashed and focused to expose the photographic medium.

photovaristor—A varistor in which the current-voltage relation may be modified by illumination. Cadmium sulfide and lead telluride exhibit such properties.

photovoltaic—Capable of generating a voltage when exposed to visible or other light radiation.

photovoltaic cell—Also called barrier-layer photocell, boundary-layer photocell, self-generating cell, solar cell, and phototronic photocell. 1. A semiconductor device that converts light into electrical energy. 2. A photosensor that generates a voltage across a pn junction as a function of the photons impinging on it. Usually made of selenium or silicon. Photosensors require no external power supply. 3. A photosensor that converts radiant flux directly to electrical current. The self-generating solar cell is very similar to an electrical battery. Barrier-layer cells are manufactured in large quantities for use in photographic exposure meters. The voltage generated by each cell is small, but series connection of a large number of cells in an array is possible. 4. A device that detects or measures radiant energy by the production of a source

of voltage proportional to the incident radiation intensity. It is possible to operate a photovoltaic cell without an additional source of voltage, since it develops a voltage. The cell detects or measures electromagnetic radiation by generating a potential at a junction (barrier layer) between two types of material on absorption of radiant energy.

photovoltaic converter—A device for converting light to electric energy by means of the photovoltaic effect.

photovoltaic effect—1. The generation of a voltage (or an electric field) in a material that is illuminated with radiation of a suitable wavelength. 2. The production of a voltage across a semiconductor pn junction due to the absorption of photon energy. The potential is caused by the diffusion of hole-electron pairs (which the incident photons cause to shift or increase) across the junction potential barrier, leading to direct conversion of a part of the absorbed energy into usable electromotive force (voltage). Usually the photovoltaic effect involves the production of a voltage in a nonhomogeneous semiconductor, such as silicon, or at a junction between two types of material. 3. The generation of a difference in electric potential between two electrodes when radiation is incident to one of them.

photovoltaic meter—An exposure cell in which a photovoltaic cell produces a current proportional to the light intensity (or area exposed) falling on the cell, and this current is measured by a sensitive current-measuring device, such as a microammeter.

photovoltaic photodetector—A photodetector that makes use of the photovoltaic effect. A source of voltage is usually not needed for the photovoltaic photodetector, since it is its own source of voltage.

photovoltaic transduction—Conversion of the measurand into a change in the voltage generated when a junction of dissimilar material is illuminated.

photox cell—A type of photovoltaic cell in which a voltage is generated between a copper base and a film of cuprous oxide during exposure to visible or other radiation.

photran—A triode pnpn-type switch of the reverse-blocking pnpn-type switch class. The photran provides optical triggering in addition to standard gate-terminal triggering.

physical configuration—The arrangement of materials, components, and wires on a structural assembly for physical strength, conservation of size, and minimal electrical interaction.

physical device—An actual peripheral hardware device, such as a line printer, terminal, card reader, or paper-tape punch, that is attached to a computer system.

physiological patient monitor—A device for automatically measuring and/or recording one or several physiological variables and responses of a patient, including heart potential, blood flow, blood pressure, pulse rate, respiration rate, temperature, etc.

pi—The Greek letter π . It designates the value of the ratio of the circumference of a circle to its diameter, approximately 3.14159.

PIC—See position-independent code.

picket fencing—Rapid flutter of the signal from a mobile station. Caused by reflections of the signal from trees and telephone poles.

pickoff—A device that produces a signal output, generally a voltage, as a function of the angle between two gimbals or between a gimbal and a base.

pickup—1. A device that converts a sound, scene, or other form of intelligence into corresponding electric

Selenium.

Silicon.

Symbol.

Photovoltaic cell.

signals (e.g., a microphone, television camera, or phonograph pickup). 2. The minimum current, voltage, power, or other value that will trip a relay. 3. Interference from a nearby circuit or system.

pickup arm — See tonearm.

pickup cartridge — The removable portion of a pickup arm. It contains the electromechanical transducing elements and the reproducing stylus.

Pickup cartridge.

pickup current — Also called pull-in current. That current at which a magnetically operated device starts to operate.

pickup head — The end of the pickup arm containing the cartridge. It is often removable from the arm and is usually called the head shell.

pickup spectral characteristic — In television, the spectral response of the camera tube including the optical parts. It converts radiation into electric signals, which are measured at the output terminals of the pickup tube.

pickup tube — A television camera image pickup tube.

pickup value (voltage, current, or power) — The minimum value that will energize the contacts of a relay. See also dropout value; hold current.

pickup voltage — That voltage at which a magnetically operated device starts to operate.

pico- — Prefix meaning 10^{-12} . (Formerly micromicro.) Letter symbol: p.

picoammeter — A sensitive ammeter that indicates current values in picoamperes.

picoampere — One-millionth of a microampere (10^{-12} ampere). Letter symbol: pA.

picrocoulomb — One-millionth of a microcoulomb (10^{-12} coulomb). Letter symbol: pC.

picrofarad — One-millionth of a microfarad (10^{-12} farad); formerly micromicrofarad. Called puff in England. Letter symbol: pF.

picrosecond — A micromicrosecond (10^{-12} second); one-thousandth of a nanosecond. Letter symbol: ps.

picrowatt — One-millionth of a microwatt (10^{-12} watt). Letter symbol: pW. Formerly called micromicrowatt.

pictorial wiring diagram — A wiring diagram containing actual sketches of components and clearly showing all connections between them.

picture black — Also called black signal. In facsimile, the signal produced at any point by the scanning of a selected area of subject copy having maximum density.

picture brightness — A measure of the brightness of the highlights in a television picture, usually measured in foot-lamberts.

picture carrier — Also called luminance carrier. The carrier frequency 1.25 MHz above the lower frequency limit of a standard NTSC television signal. In color television, this carrier is used for transmitting luminance information; the chrominance subcarrier, which is 3.579545 MHz higher in frequency, transmits the color information.

picture element — Also called elemental area, critical area, scanning spot, or recording spot. 1. In facsimile, that portion of the subject copy that is seen by the scanner at any instant. It can be considered a square area having dimensions equal to the width of the scanning line. 2. In television, any segment of a scanning line whose dimension along the line is exactly equal to the nominal line width. The area being explored at any instant in the scanning process. 3. See pixel.

picture freeze — A TV mode that makes it possible to "freeze" an image to study specific details at ease.

picture frequency — The number of complete pictures scanned per second in a television system.

Picture-in-Picture — Abbreviated PIP.

picture line standard — The total number of horizontal lines in a complete television image. The standard in the United States is 525 lines (NTSC standard).

picture monitor — A cathode-ray tube and its associated circuits arranged for viewing a television picture.

picture signal — In television, the signal resulting from the scanning process.

picture-signal amplitude — The difference between the white peak and the blanking level of a video signal.

picture-signal polarity — The polarity of the signal voltage that represents a dark area of a scene given with respect to the signal voltage representing a light area. Expressed as black negative or black positive.

picture size — The usable viewing area on the screen of a television receiver, measured in square inches.

picture-synchronizing pulse — See vertical-synchronizing pulse.

picture transmission — Electric transmission of a shaded (halftone) picture.

picture transmitter — See visual transmitter.

picture tube — 1. The cathode-ray tube in a TV monitor or receiver on which the picture is produced by variation of the beam intensity as the beam scans the raster. 2. See kinescope, 1.

picture-tube brightener — An accessory added to an aging picture tube to increase the image brightness and thereby extend its useful life. The brightener raises the filament voltage and thereby increases the electron emission from the cathode.

PIDD — Acronym for *positive identification and detection*. A passive terminal homing device for identifying ships by radar signatures.

Pierce oscillator — Basically a Colpitts oscillator in which a piezoelectric crystal is connected between the plate and grid (or collector and base, or drain and gate). Voltage division is provided by the interelectrode capacitances of the circuit.

pie winding — A winding constructed from individual washer-shaped coils called pies.

piezodielectric — Pertaining to a change in dielectric constant under mechanical stress.

Pierce oscillator.

piezoelectric—1. The property of certain crystals that produce a voltage when subjected to a mechanical stress, or undergo mechanical stress when subjected to a voltage. (The word is derived from the Greek *piezein*, meaning to squeeze or press.) 2. A speaker drive principle using a ceramic element that expands or bends under the application of a signal voltage. This deflection generates a sound output. Used in some tweeter designs. 3. The conversion of mechanical energy, such as mechanical stress, to electric energy.

piezoelectric accelerometer—1. Basically a crystalline material that, when force is applied, generates a charge. Through the incorporation of a mass in direct contact with the crystal, an acceleration transducer is produced. 2. A transducer that converts dynamic force (vibration) into electrical energy, i.e., it is a charge generator.

piezoelectric axis—With respect to a crystal, one of the paths or axes that will exhibit a piezoelectric charge when subject to tension or compression.

piezoelectric crystal—1. A piece of natural quartz or other crystalline material capable of demonstrating the piezoelectric effect. A quartz crystal, when ground to certain dimensions, will vibrate at a desired radio frequency when placed in an appropriate electric circuit. 2. A substance that has the ability to become electrically polarized and has strong piezoelectric properties in it, so cut as to emphasize the coupling to some distinct mechanical mode of the crystal. Used as an electromechanical transducer.

piezoelectric crystal cut—The orientation of a piezoelectric crystal plate with respect to the axes of the crystal. It is usually designated by symbols; e.g., GT, AT, BT, CT, and DT identify certain quartz-crystal cuts having very low temperature coefficients.

piezoelectric crystal element—A piece of piezoelectric material cut and finished to a specified shape and orientation with respect to the crystallographic axes of the material.

piezoelectric crystal plate—A piece of piezoelectric material cut and finished to specified dimensions and orientation with respect to the crystallographic axes of the material and having two essentially parallel surfaces.

piezoelectric crystal unit—A complete assembly comprising a piezoelectric crystal element mounted, housed, and adjusted to the desired frequency, with means for connecting it into an electric circuit. Such a device is commonly employed for frequency control or measurement, electric wave filtering, or interconversion of electric and elastic waves.

piezoelectric device—A substance that generates an electric voltage when bent, squeezed, or twisted. Conversely, when a voltage is applied, it will twist, bend, expand, or contract.

piezoelectric effect—1. The mechanical deformity of certain natural and synthetic crystals under the influence of an electric field. This effect is used in high-precision oscillators and certain high-frequency filters. 2. The property of certain natural and synthetic crystals to produce a voltage when subjected to mechanical stress (compression, expansion, twisting, etc.). 3. The interaction between electrical and mechanical stress-strain factors in a material. In particular natural and synthetic crystals, i.e., those that have no center of symmetry, it is a property, and the effect is linear in a field of strength. Thus, when a quartz crystal is compressed, an electrostatic voltage is generated across it, or when an electric field is applied, the crystal may expand or contract in particular directions. 4. The property of some crystals such as quartz, tourmaline, and Rochelle salt, when compressed in certain directions, of showing electric charges of opposite polarity on pairs of the crystal face. The charges are proportional to the pressure, and disappear when the pressure is removed.

piezoelectricity—The phenomenon whereby certain crystalline substances, such as barium titanate, generate electrical charges when subjected to mechanical deformation. The effect was first noticed by the Curie brothers in the 1880s as a result of extensive study of the symmetry of crystalline materials. The reverse effect also occurs.

piezoelectric loudspeaker—*See* crystal loudspeaker.

piezoelectric material—A material that generates an electrical output when subjected to a mechanical stress.

piezoelectric microphone—*See* crystal microphone.

piezoelectric oscillator—A crystal-oscillator circuit in which the frequency is controlled by a quartz crystal. *See also* Pierce oscillator.

piezoelectric pickup—1. A type of cartridge whose generating element is a ceramic, crystal, or electret that generates electricity when bent, twisted, or stressed. The output of such cartridges can be fairly high. It is also proportional to the amplitude of the stylus motion, rather than stylus velocity, and so requires no equalization. Both these factors allow the use of simpler input circuits, one reason why piezoelectric (chiefly ceramic) cartridges are used in low-cost equipment. 2. *See* crystal pickup.

piezoelectric pressure gage—An apparatus for measuring or recording very high pressures. The pressure is applied to quartz discs or other piezoelectric crystals. The resultant voltage, after amplification, is then measured or is recorded with an oscillograph.

piezoelectric speaker—*See* crystal speaker.

piezoelectric transducer—Also called ceramic or crystal transducer. A transducer that depends for its operation on the interaction between the electric charge and the deformation of certain asymmetric crystals having piezoelectric properties.

piezoelectric transduction—The conversion of the measurand into a change in the electrostatic charge or voltage generated by mechanically stressed crystals.

piezoid—The finished crystal blank. It may also include the electrodes for making contact with the crystal.

piezo-optical transducer—A structure consisting of a thin film of liquid crystal sandwiched between light-polarizing filters that have received a surface lubricant. Depending on the motion, the transducer acts as a highly sensitive detector by virtue of the sensitivity of the liquid crystal that is made to float by the lubricant between the plates. It produces a readily visible and colorful optical pattern that is dependent on the amount of disturbance.

piezoresistance—Resistance that changes with pressure.

Piezoelectric transducer.

piezoresistive transduction—A change in the resistance of a conductor or semiconductor caused by a change in the mechanical stress applied to it.

piggyback—See voltage corrector.

piggyback control—See cascade control.

piggyback twistor—An electrically alterable, non-destructive-readout information-storage device that consists of a thin, narrow tape of magnetic material wound spirally around a fine copper conductor. A second similar tape is wrapped on top of the first to sense the stored information. A binary digit is stored at the intersection of a copper strap and a pair of these twistor wires.

pigtail—1. Either a wire attached for terminating purposes to a shield, or a conductor extending from a small component. 2. The termination of a capacitor winding to its lead. 3. The disc-shaped head, at the end of a lead, that is attached to a capacitor winding. 4. A short wire extending from an electric or electronic device to serve as a jumper or ground connection.

pigtail splice—A splice made by tightly twisting the bared ends of parallel conductors together.

pigtail wire—1. Fine-stranded, extra-flexible, rope-lay lead wire. 2. A short piece of wire attached to a shield for terminating purposes, or the conductor extending from a small component.

pile—1. A nuclear reactor. So called because early reactors were piles of graphite blocks and uranium slugs. 2. (Voltaic) Invented by Volta in 1800, it was the first primary battery known to the modern world. The pile consisted of an arrangement of pairs of discs of copper and zinc, each pair separated by a disc of moistened pasteboard. Later Volta arranged a series of cups filled with brine, each containing a zinc and copper plate, and by connecting these together obtained an electric current.

pileup—Also called stack. 1. On a relay, a set of contact arms, assemblies, or springs fastened one on top of the other with layers of insulation separating them. 2. A departure from the base line because of a rapid accumulation of pulses.

pill—A microwave stripline termination.

pillbox antenna—A cylindrical parabolic reflector enclosed by two plates perpendicular to the cylinder and spaced to permit propagation of only one mode in the

desired direction of polarization. It is fed on the focal line.

pilot—1. In a transmission system, a signal wave, usually a single frequency, transmitted over the system to indicate or control its characteristics. 2. In a tape relay, instructions appearing in a routing line, relative to the transmission or handling of that message.

pilot cell—The storage-battery cell selected because its temperature, voltage, and specific gravity are assumed to be those of the entire battery.

pilot channel—A very narrow-band channel over which a single frequency, the pilot frequency, is transmitted to operate trouble alarms or automatic level regulators, or both.

pilot contacts—Contacts whose opening, closing, or transfer govern an operation of relays or similarly controlled devices.

pilot holes—Also called manufacturing holes or fabrication holes. Holes on a printed circuit board used as guides during manufacturing operations. Mounting holes in a part are sometimes used as pilot holes.

pilot lamp—A light that indicates whether a circuit is energized.

pilot light—Also known as a monitor light. 1. A light that, by means of position or color, indicates whether a control is functioning. 2. A light that indicates which of a number of normal conditions of a system or device exists. It is unlike an alarm light, which indicates an abnormal condition.

pilot regulator—A device for maintaining the receiving level of a carrier-derived circuit constant under varying attenuation conditions of the transmission line.

pilot spark—A low-power preliminary spark used in a gas-discharge tube to produce an ionized path for the large main spark discharge.

pilot subcarrier—A subcarrier used as a control signal in the reception of compatible FM stereophonic broadcasts.

pilot tone—1. A single frequency sent over a narrow channel to cause an alarm or automatic control to operate. 2. The signal included with the stereo information and applied in a subchannel on the FM signal, which is used to reform the suppressed subcarrier and synchronize the switching of the detectors in the stereo decoder. Pilot-tone frequency is 19 kHz (broadcast at the equivalent of 10 percent FM modulation), and doubling this (38 kHz) gives the subcarrier frequency. The pilot tone also activates the stereo indicator light.

pilot-type device—A device used in a circuit for control apparatus that carries electrical signals for directing the performance but does not carry the main power current.

pilot wire—An auxiliary conductor used with remote measuring devices or for operating apparatus at a distance.

pilot-wire regulator—An automatic device for controlling adjustable gains or losses associated with transmission circuits to compensate for transmission changes caused by temperature variations, the control usually depending on the resistance of a conductor or pilot wire having substantially the same temperature conditions as the conductors of the circuit being regulated.

pi mode—A mode of magnetron operation in which the fields of successive anode openings facing the interaction space differ in phase by π radians.

pin—Also called a prong or base pin. A terminal on a connector, plug, or tube base.

pinboard—A perforated board into which pins may be inserted manually to control the operation of equipment.

pinch effect—1. The result of an electromechanical force that constricts, and sometimes momentarily ruptures, a molten conductor that is carrying a high-density current. 2. In the reproduction of lateral recordings, the pinching of the reproducing stylus tip twice each cycle due to a decrease in the groove angle cut by the recording stylus during the swing from a negative to a positive peak. 3. The self-contraction of a plasma column carrying a large current due to the interaction of this current with the magnetic field it produces. The current required for such an effect is on the order of 105 amperes. If the current is in the form of a short pulse, a radically imploding shock wave is generated.

pinch-off—1. In a field-effect transistor, a condition in which the gate bias causes the depletion region to extend completely across the channel, with a resulting cessation of drain current. 2. The voltage required to stop majority current flow in an FET.

pinch-off voltage—The gate voltage of a field-effect transistor that blocks the current for all source-drain voltages below the junction breakdown value. Pinch-off occurs when the depletion zone completely fills the area of the device.

pinch resistor—A monolithic silicon resistor derived from a p-base diffusion resistor by superimposing an n+ emitter diffusion over the resistor. As a result, the surface of the p resistor reverts to n-type material, and a narrow “pinched” resistor is left under the n+ diffusion. A pinch resistor features 10,000 ohms per square, but it is limited to low voltages, and it has a high temperature coefficient.

Pinch resistor.

pinch roller—1. An idling roller used to press a tape against the capstan to cause advance. A friction clamp is used with the roller, as a brake to stop perforated tape. 2. A rubber or neoprene wheel that presses the tape against the capstan during recording or play.

pinch wheel—1. See pressure roller. 2. See idler.

pin connection—Connections made to the base of pins in a vacuum tube. They are identified by the following abbreviations: NC, no connection; IS, internal shield; IC, internal connection (not an electrode connection); P, plate; G, grid; SG, screen grid; SU, suppressor; K, cathode; H, heater; F, filament; RC, ray-control electrode; and TA, target.

pin contact—A male-type contact, usually designed to mate with a socket of female contact. It is normally connected to the “dead” side of a circuit.

pincushion distortion—1. Distortion that results in a monotonic increase in radial magnification in the reproduced image away from the axis of symmetry of the electron optical system. The four sides of the raster are curved inward, leaving the corners extending outward. 2. Distortion in a television picture that makes all sides appear to bulge inward. 3. A form of geometrical distortion in a CRT image that results in the picture resembling

a pincushion rather than a well-defined rectangle. Some monitors include controls to correct this effect.

Pincushion distortion.

pincushioning—A video-display defect in which the image appears to bend inward toward the middle of the screen.

pin diode or PIN diode—1. A diode made by diffusing the semiconductor with p dopant from one side and n dopant from the opposite side, with the process so controlled that a thin intrinsic (i) region separates the p and n regions. The storage time of the pin diode is long enough that it cannot rectify at microwave frequencies. Instead, it behaves as a variable resistor with its value controlled by a dc bias current. Therefore, this type of diode is well suited for use as a variable microwave attenuator. 2. A pn silicon junction with a layer of intrinsic or high-sensitivity silicon between the p and n regions. When forward biased, the pin diode behaves as a resistance from dc to microwave frequencies. The value of the resistance depends on the forward current. Under reverse bias, the resistance is very high. The pin diode may be used as an electrically variable resistance or attenuator. Its uses at microwave frequencies are for switching and modulating microwave signals and as an electrically variable attenuator. It can perform switching in a few nanoseconds and handle peak powers of hundreds of watts. 3. A current-controlled resistor at radio and microwave frequencies. A silicon semiconductor diode in which a high-resistivity intrinsic i-region is sandwiched between a p-type and n-type region. When the pin diode is forward biased, holes and electrons are injected into the i-region. These charges do not immediately annihilate each other; instead, they stay alive for an average time called the carrier lifetime. This results in an average stored charge, Q , that lowers the effective resistance of the i-region. When the pin diode is at zero or reverse bias, there is no stored charge in the i-region and the diode appears as a capacitor, shunted by a parallel resistance. 4. A diode that has an undoped semiconductor region, referred to as an intrinsic layer, between the n and p doped layers. The intrinsic layer provides low junction capacitance that changes very little as reverse bias is changed. Used mostly as a microwave switch or attenuator.

pin-diode attenuator—A two-port network consisting of two or more pin diodes controlled by a driver circuit. At microwave frequencies, the diodes act as a small value of capacitance shunted by a resistance that can be varied over a range of about 2 to 10,000 ohms through control of the bias current by the driver circuit.

pine-tree array—An array of dipole antennas aligned vertically (termed the radiating curtain), behind which and approximately a quarter wavelength away is a parallel array of dipole antennas forming the reflecting curtain.

pi network—1. A network composed of three branches, all connected in series with each other to form

a mesh. The three junction points form an input terminal, an output terminal, and a common input and output terminal. 2. A network consisting of three impedance elements, one bridged across the input, one bridged across the output, and the third in series between one input terminal and one output terminal. 3. A tuned circuit at the output stage of a transmitter to match it to the antenna or feedline.

Pi (π) network.

pinfeed platen—In a computer, a cylindrical platen having integral rings of pins that engage perforated holes in the paper, thus permitting feeding of the paper.

ping—A sonic or ultrasonic pulse of predetermined width.

ping-pong—A programming technique in which two magnetic tape units are used for multiple-reel files. Automatic switching between the two units is carried out until the entire file is processed.

ping-pong-ball effect—The bouncing of sound back and forth between the two sides of a stereophonic reproducing system.

pinhole—1. A small opening, occurring as an imperfection, extending through the thickness of a substance. 2. A minute hole through a layer or pattern. 3. Small hole occurring as an imperfection that penetrates entirely through an applied material to the substrate (e.g., holes in semiconductor insulating oxides, screened resistors, thin-film elements).

pinhole detector—A photoelectric device that detects extremely small holes and other defects in moving sheets of material, and often actuates sorting equipment that automatically rejects defective sheets.

pinion—Of two gears that mesh, the one with the fewer teeth.

pin jack—A single-conductor jack having a small opening into which a plug tipped with a metal pin can be inserted.

pink noise—1. Noise whose amplitude is inversely proportional to frequency over a specified range. Equal energy distribution occurs in any octave bandwidth within that range. Pink noise is very pleasing to the human ear. Many people feel relaxed listening to the pattering of rain (a close approximation of pink noise). Other examples include the sound of surf and a shower stream. 2. A complete mixture of all frequencies in one signal characterized by equal energy per octave. This means that there is an equal amount of energy between 20 and 40 Hz, 80 and 160 Hz, or 620 and 1240 Hz. 3. Random noise modified to have an equal amount of energy in each octave. The octave from 10,000 to 20,000 Hz occupies a 10,000-Hz bandwidth, whereas the octave from 5000 Hz to 10,000 Hz occupies only 5000 Hz bandwidth, but due to a 6-dB/octave roll-off, both octaves contain equal levels of pink noise energy. 4. Random electrical noise that has constant energy per octave. Pink noise can be produced from white noise by putting it through a filter that has a slope of -3 dB per octave.

PINO—Acronym for positive input, negative output.

pinout—1. A list or diagram that shows how the individual wires in a cable or connector are used. 2. A

diagram showing connections to an integrated circuit or transistor.

pinouts—The external wires or pins on a module (generally having a circuit function).

pins—The leads emerging from an IC package.

pin sensing—A process in which a device using a punched card generates digital data by sensing the opening and closing of switches.

pip—See blip, 1.

PIP—Abbreviation for Picture-in-Picture. A feature available in some TV receivers that makes it possible to watch one picture on the screen, while at the same time keeping track of another program in the PIP “window.” The two images are readily switched back and forth.

piped program—A program transmitted over telephone wires, usually from one studio to another.

pipeline—A processor design approach whereby instruction execution takes place in a series of units arranged so that several units can be simultaneously processing the appropriate parts of several instructions.

pipeline computers—Computers that execute serial programs only.

pipelining—1. A hardware arrangement that permits different sections of a bit-slice processor to work simultaneously instead of sequentially, thus speeding up processing. 2. Beginning one instruction sequence before another has been completed. Once a technique used on supercomputers, pipelining is now used to speed execution on machines of all sizes. 3. A computer design technique in which execution of a new task is started before the preceding task is completed.

pip-matching display—A navigational display in which the received signal appears as a pair of blips. The desired quantity is measured by comparing the characteristics.

pi point—The frequency at which the insertion phase shift of an electric structure is 180° or an integral multiple of 180° .

piracy—Illegal copying of diskettes or other copyrighted material that is then offered for sale.

Pirani gage—A bolometric vacuum gage for measuring pressure. Its operation depends on the thermal conduction of the gas present. The pressure being measured is a function of the resistance of a heated filament, ordinarily over a range of 10^{-1} to 10^{-4} mm Hg.

pirate—An unlicensed, unauthorized, and illegal broadcasting station.

piston—Also called a plunger. In high-frequency communications, a conducting plate that can be moved along the inside of an enclosed transmission path to short out high-frequency currents.

piston action—The movement of a speaker cone or diaphragm when driven at the bass audio frequencies.

piston attenuator—An attenuator, generally used at microwave frequencies, whose amount of attenuation can be varied by moving an output coupling device along its longitudinal axis.

pistonphone—A small chamber equipped with a reciprocating piston of measurable displacement. In this way, a known sound pressure can be established in the chamber.

PII—Abbreviation for programmable interval timer. An IC chip with a separate clock and several registers, used to count time independently of the MPU, for real-time applications. At the end of a time period, it sets a flag or generates an interrupt, or merely stores the time elapsed.

pitch—1. That attribute of auditory sensation by which sounds may be ordered on a scale extending from low to high (e.g., a musical scale). 2. The distance

between two adjacent corresponding threads of a screw measured parallel to the axis. 3. The distance between the peaks of two successive grooves of a disc recording. 4. A term applied to a musical tone that is used as a standard for tuning, singing, etc. Standard U.S. and European pitch is based on $A = 440$ Hz. When the pitch is raised one octave, the frequency is twice the original.

pitch control—1. A circuit that permits the speed of a tape transport's motor to be varied slightly to raise and lower the musical pitch of the recording or to slightly lengthen or shorten playing time. 2. A circuit that permits a turntable's speed to be varied slightly to raise and lower the musical pitch of the recording being played (hence, the name) or to slightly lengthen or shorten playing time.

pits—1. Small holes occurring as imperfections that do not penetrate entirely through the printed element. 2. Depressions produced in metal or ceramic surfaces by nonuniform deposition.

pitted contact—An electrical contact that has numerous discrete hollows in its surface.

PIV—Abbreviation for peak inverse voltage.

pivot—A low-friction bearing in the support of a tonearm that allows it freedom of movement in vertical and horizontal planes. In lower-priced tonearms, it may be a simple point-in-cup pivot. More expensive tonearms usually have precision ball bearings or knife-edge pivots.

pivot and jewel—A method of suspending the moving coil or moving iron vane of a meter in a magnetic field. A glass jewel and steel pivot.

PIV rating—See PRV rating.

pixel—Contraction of picture element. 1. A spatial resolution element. It is the smallest distinguishable and resolvable area in an image, as, for example, displayed on a CRT monitor. It can also describe the smallest distinguishable variation over time in a signal sequence. (The term pixel is not, strictly speaking, applicable to an analog image, but it is sometimes equated to limiting resolution. In general, however, actual pixel resolution is less than limiting resolution.) 2. The smallest controllable picture element in a digital video image. The CRT screen is divided into a rectangular grid of pixels of the same size and shape. In the vertical direction, the highest picture resolution occurs when each pixel is one scan line high. Horizontal resolution is typically limited by the speed at which the CRT electron gun can switch on and off during a horizontal scan. For square pixels, which are normally more desirable than horizontally elongated rectangles, the smallest possible pixel size is usually determined by this horizontal resolution limit. Normally, a square pixel is two or more scan lines high. (In North America, the standard television picture is normally 525 lines high, though partly cropped.) 3. Picture element or picture cell. A term used to describe the information contained in one unit of display surface. (For example, a horizontal resolution of 1700 pixels per line.) 4. The smallest picture element, made up of tricolor phosphor cells. In raster-scan systems the computer divides the screen into such points, whose number depends on the resolution selected. 5. A small element of a scene, or picture element, in which an average brightness value is determined and used to represent that portion of the scene. Pixels are arranged in a rectangular array to form a complete image of the scene. 6. The smallest unit of a video display, usually too small to be detected by the naked eye. Pixels, illuminated dots of glowing phosphor, can vary in size and shape depending on the monitor and the graphics mode. Display quality is often measured by pixel resolution—the number of dots on the screen measured in width-by-height fashion. 7. Smallest independently addressable display area; one full-color pixel requires three phosphor dots, one for each primary color.

PLA—Abbreviation for programmable logic array.

place—See column.

plaintext—A message in ordinary language, such as English.

planar—1. Lying essentially in a single plane. 2. Constructed in layers or planes. 3. A semiconductor fabrication technique in which the semiconductor device chips are protected by an oxide passivation layer throughout the various stages of fabrication. The planar process thus represents a synthesis of the separate oxide-layer functions involved in the photolithographic etching of diffusion masking and in chip passivation.

planar ceramic tube—An electron tube constructed with parallel planar electrodes and a ceramic envelope.

planar devices—See planar process.

planar diffusion—Technique used to manufacture semiconductors having diffused pn junctions. All the junctions emerge at the top surface of the wafer.

planar diode—A diode containing planar electrodes lying in parallel planes.

planar display—A display in which the light-emitting segments or elements are all mounted in a single plane.

planar mask—A shadow or aperture mask that has no curvature; one that is perfectly flat.

planar module—A packaged module wherein the individual components are positioned and terminated flat or parallel with the plane of the substrate.

planar network—A network in which no branches cross when drawn on the same plane.

planar process—1. The technology used in fabricating semiconductor devices wherein all pn junctions terminate in the same geometric plane. An oxide is formed at the surface for the purpose of stabilizing the parameters (passivating). 2. Semiconductor fabrication technology that uses silicon dioxide as a masking agent and produces components on a single plane.

planar silicon photoswitch—Abbreviated PSPS. Essentially a complementary silicon-controlled rectifier. Like the LASCR, it can be triggered by light. In addition, a negative signal (with reference to the anode) at the anode gate terminal can trigger the device.

planar soldering—A soldering method in which the printed circuit assembly is held loosely in a carrier. This freedom of movement allows the printed circuit assembly to float on the still surface of the solder bath, equalizing the thermogradient throughout the entire assembly.

planar technique—The formation of p-type and/or n-type regions in a semiconductor crystal by diffusing impurity atoms into the crystal through holes in an oxide mask, which is on the surface. The latter is left to protect the junctions so formed against surface contamination.

planar transistor—1. A diffused transistor in which the emitter, base, and collector regions come to the same plane surface. Their junctions are protected by a material such as silicon oxide. The manufacturing process consists of an oxide-masking technique in which the

Planar transistor.

silicon oxide is formed by adding oxygen or water vapor to the atmosphere of a diffusion furnace. The thickness of the oxide layer is a function of time, temperature, and the amount of oxidizing agent. 2. A junction transistor manufactured by a process in which the surface of a chip is passivated with a thin film of oxide, dopants being introduced by successive etching and diffusion.

planchet—A small metal container or sample holder for radioactive materials undergoing radiation measurements in a proportional counter or scintillation detector.

Planckian locus—A line drawn on a chromaticity diagram to represent light radiation from a reference blackbody at 2000 to 10,000 kelvins (K).

Planck's constant—Symbolized by h . The constant representing the ratio of the energy of any radiation quantum to its frequency. It has the dimension of action (energy \times time) and a numerical value of 6.547×10^{-27} erg-second. Its significance was first recognized by the German physicist Max Planck in 1900.

Planck's distribution—An equation that describes the entire distribution of energy radiated from a blackbody as a function of wavelength, based on quantum mechanics.

Planck's radiation law—An expression representing the spectral radiance of a blackbody as a function of the wavelength and temperature.

plane—1. A screen of magnetic cores. Planes are combined to form stacks. 2. A surface such that a straight line that joins any two of its points lies entirely in that surface.

plane earth—Earth that is considered to be a plane surface. Used in ground-wave calculations.

plane-earth attenuation—Attenuation of an electromagnetic wave over an imperfectly conducting plane earth in excess of that over a perfectly conducting plane.

plane-earth factor—Ratio of the electric field strength that would result from propagation over an imperfectly conducting plane earth to that over a perfectly conducting plane.

plane of a loop—An infinite imaginary plane that passes through the center of a loop and is parallel to its wires.

plane of polarization—For a plane-polarized wave, the plane containing the electric field vector and the direction of propagation.

plane-polarized wave—At any point in a homogeneous isotropic medium, an electromagnetic wave with an electric field vector that at all times lies in a fixed plane containing the direction of propagation.

planetary electron—One of the electrons moving in an orbit or shell around the nucleus of an atom.

plane wave—A wave in which the wavefronts are everywhere parallel planes normal to the direction of propagation.

plan-position indicator—Abbreviated PPI. Also called P-display. A type of presentation on a radar indicator. The signal appears as a bright spot, with range indicated by the distance of the spot from the center of the screen, and the bearing indicated by the radial angle of the spot.

plasma—1. A wholly or partially ionized gas in which the positive ions and negative electrons are roughly equal in number. Hence, the space charge is essentially zero. 2. The region in which gaseous conduction takes place between the cathode and anode of an electric arc. 3. An electrically conductive gas comprised of neutral particles, ionized particles, and free electrons but which, taken as a whole, is electrically neutral. 4. A gas at an extremely high (20,000 kelvins) temperature and completely ionized. It is therefore conductive and affected

by magnetic fields. Plasma is sometimes referred to as the fourth state of matter.

plasma-cathode electron gun—An electron-beam gun in which plasma that is generated within a low-voltage hollow-cathode discharge serves as the source of electrons.

plasma deposition—The spraying of highly excited atomic particles onto a surface. Heat, commonly obtained by electric arc or hydrogen flame, is the source of excitation. Almost any elementary material can be applied to almost any surface by this method. Disadvantages are grossness of the spray process and high temperatures.

plasma diode—A thermodynamic engine with electrons as the working fluid, the potential energy of which is converted to a useful output.

plasma display—A display in which the emitted light is produced by ionized gas.

plasma engine—A reaction engine using electrically accelerated plasma as the propellant.

plasma etching—An etching process using a cloud of ionized gas as the etchant.

plasma frequency—A natural frequency for coherent electron motion in a plasma.

plasma jet—A high-temperature stream of electrons and positive ions produced by the magnetohydrodynamic effect of a strong electrical discharge.

plasma laser—A laser that operates with light collectively emitted by free electrons in the plasma state. This plasma is a dense beam of electrons traveling at speeds approaching the speed of light.

plasma length—See Debye length.

plasma oscillation—Electrostatic or space-charge oscillations in a plasma that are closely related to the plasma frequency. There is usually enough damping due to electron collisions to prevent self-generation of the oscillations. They can be excited, however, by such techniques as shooting a modulated electron beam through the plasma.

plasma physics—The study of highly ionized gases. Many phenomena not exhibited by uncharged gases are associated with plasma physics.

plasma sheath—An envelope of ionized gas that surrounds an object moving through an atmosphere at a hypersonic velocity. The plasma sheath affects radio-wave transmission, reception, and diffraction.

plasma thermocouple—An electronic device in which the heat from nuclear fission is converted directly into electric power.

plasmatron—A helium-filled current amplifier that combines the grid-control characteristics and linearity of a vacuum triode with the extremely low internal impedance of a thyatron.

plastic-clad silica fiber—A fiber composed of a silica glass core with a transparent plastic cladding.

plasticizer—A substance added to a plastic to produce softness and adhesiveness in the finished product.

PLAT—Acronym for pilot landing aid television. A system in which television cameras cover aircraft landings on a carrier from several angles, allowing the landing personnel to talk the pilot down with increased precision. Recordings can be made for future reference.

plate—Preferably called the anode. 1. The principal electrode to which the electron stream is attracted in an electron tube. 2. One of the conductive electrodes in a capacitor. 3. One of the electrodes in a storage battery. 4. See printed circuit board.

plateau—In the counting-rate-versus-voltage characteristic of a radiation counter tube, that portion in which the counting rate is substantially independent of the applied voltage.

plateau length—The applied-voltage range over which the plateau of a radiation counter tube extends.

plate-bypass capacitor—A capacitor connected between the plate and cathode of a vacuum tube to bypass high-frequency currents and, thus, keep them out of the load. *See also* anode-bypass capacitor.

plate characteristic—A graph showing how changes in plate voltage affect the plate current of a vacuum tube.

plate circuit—The complete external electrical circuit between the plate and cathode of an electron tube.

plate-circuit detector—A detector that functions by virtue of its nonlinear plate-current characteristic.

plate conductance—The in-phase component of the alternating plate current divided by the alternating plate voltage, all other electrode voltages being maintained constant.

plate current—Electron flow from the cathode to the plate inside an electron tube.

plate-current saturation—An occurrence in a vacuum tube when the plate overcomes any other charge in the tube.

plate detection—The operation of a vacuum-tube detector at or near plate-current cutoff so that the input signal is rectified in the plate circuit.

plate dissipation—The amount of power lost as heat in the plate of a vacuum tube.

plated resist—A material electroplated on conductive areas to make them impervious to etching.

plated-through hole—1. A connection between upper and lower conductive patterns formed when metal is deposited on the walls of a hole in a double-sided or multilayer printed-circuit board. Through-board continuity is thus established. 2. A hole formed by deposition of metal on the sides of the hole and on both sides of a printed circuit board to provide electrical connection from the conductive pattern on one side to that on the opposite side of the printed circuit board.

plated-wire memory—A memory consisting of wires that are coated with a magnetic material. The magnetic material may be magnetized in either of two directions to represent 1s and 0s.

plate efficiency—Also called the anode efficiency. Ratio of load-circuit power (alternating current) to plate power input (direct current).

plate impedance—Also called plate-load impedance.

plate-input power—In the last stage of a transmitter, the direct plate voltage applied to the tubes times the total direct current flowing to their plates, measured without modulation.

plate keying—Keying done by interrupting the plate supply circuit.

plate-load impedance—Also called the anode-load impedance and plate impedance. The total impedance between the anode and cathode of a vacuum tube, exclusive of the electron stream.

plate modulation—Also called anode modulation. Modulation produced by applying the modulating voltage to the plate of any tube in which the carrier is present.

platen—1. A backing structure (usually cylindrical) against which a printing mechanism strikes in producing an impression. 2. In a printer, a metal plate or roller that forms a surface for the striking mechanism.

plate neutralization—Also called anode neutralization. Neutralizing an amplifier by shifting a portion of the plate-to-cathode ac voltage 180° and applying it to the grid-to-cathode circuit through a capacitor.

plate power input—Also called the anode power input. The dc power (mean anode voltage times current) delivered to the plate (anode) of a vacuum tube.

Plate neutralization.

plate power supply—*See* anode power supply.

plate pulse modulation—Also called anode pulse modulation. Modulation produced in an amplifier or oscillator by applying externally generated pulses to the plate circuit.

plate resistance—The plate-voltage change divided by the resultant plate-current change in a vacuum tube, all other conditions being fixed.

plate saturation—Also called anode or voltage saturation. The point at which the plate current of a vacuum tube no longer increases as the plate voltage does.

plate supply—*See* anode supply.

plate-to-plate impedance—The load impedance between the two plates in a push-pull amplifier stage.

plate voltage—The dc voltage between the plate and cathode of a vacuum tube.

plate winding—A transformer winding connected to the plate circuit of a vacuum tube.

plating—1. The deposition of a metal layer on a substrate surface by electrolytical or certain chemical means. The materials include gold, copper, solder, etc. The functions of the metal plate vary, including corrosion protection, solderability enhancement, etch resist, bonding for lead frames, and electrical connection, among others. 2. The overlaying of a thin coating of metal or metallic components to improve conductivity, provide for easy soldering, or prevent rusting or corrosion. 3. The application of one metal over another by electrolysis.

plating anode—Usually, a pure form of the metal being plated. The workpiece being plated is the cathode.

plating resist—Any material that when deposited on conductive areas prevents plating of the areas it covers.

plating up—The process consisting of the electrochemical deposition of a conductive material on the base material (surface, holes, etc.) after the base material has been made conductive.

plating void—The area of absence of a particular metal from a specific cross-sectional area.

platinotron—A cross-field vacuum tube used to generate and amplify microwave energy. It resembles the magnetron, except that it has no resonant circuit and has two external rf connections instead of only one.

platinum—A heavy, almost white metal that resists practically all acids and is capable of withstanding high temperatures.

platinum contacts—Used where currents must be broken frequently (e.g., in induction coils and electric bells). Sparking does not damage platinum as much as it does other metals. Hence, a cleaner contact is assured with minimum attention.

platter—1. A popular term for phonograph records and transcriptions. 2. The flat disc that supports the record and is turned by a motor at a constant speed. Usually machined from a nonferrous alloy but is sometimes a lightweight stamped or pressed disc.

playback—The reproduction of a tape recording or disc through an amplifier and speaker or phones.

playback head—1. The magnetic assembly on a tape recorder that responds to the recorded pattern on the tape and develops a signal representing that pattern to feed to the preamplifier. In some tape machines, the playback and recording head are the same device; in others they are separate units. 2. Magnetic head used to pick up a signal from a tape.

playback loss—*See* translation loss.

player—A software application that permits viewing or playback of content such as audio, video, or movie files in primarily a linear fashion, although random indexing or control of playback may be permitted. As opposed to a browser. *See also* viewer.

playing weight—1. Downward force of a pickup on a record. Sometimes called stylus pressure. 2. The downward force required on the pickup stylus to keep it in the groove and to counter the mechanical reactions of replay.

PLCC—Abbreviation for plastic leaded chip carrier. A leaded quad package—a replacement for the plastic DIP (dual in-line package) in surface-mount applications. External connections consist of leads around all four sides of the package.

PLD—Abbreviation for programmable logic device. A semiconductor device containing transistors that can be interconnected electronically by users to perform various logic functions. *See also* FPLA.

plethysmograph—An instrument for detecting variations of blood volume in the tissues during the cardiac cycle. *See also* electrical-impedance cephalography; finger plethysmograph.

pliers—1. A small pair of pincers. 2. An instrument having two short handles extended into pivoted jaws suitable for grasping or cutting.

pliodynatron—A four-element vacuum tube with an additional grid, which is maintained at a higher voltage than the plate to obtain negative-resistance characteristics.

plotron—An industrial-electronic term for a hot-cathode vacuum tube having one or more grids.

PLL or plil—Abbreviation for phase-locked loop. 1. A circuit containing a voltage-controlled oscillator whose output phase or frequency can be steered to keep it in sync with a reference source. A PLL circuit is generally used to lock onto and up-convert the frequency of a stable source. 2. An electronic circuit that consists of a phase detector, low-pass filter, and voltage-controlled oscillator. A PLL can be used as an FSK demodulator or to synchronize a terminal's internal clock to the received bit stream.

plot—*See* print.

plotter—1. A device that produces an inscribed visual display of the variation of a dependent variable as a function of one or more other variables. 2. A device for presenting computer output in graphical form instead of a printed listing. 3. A visual display or board in which a dependent variable is graphed by an automatically controlled pen or pencil as a function of one or more variables. 4. A device used to make a permanent copy of a display image. 5. An output device that provides data in pictorial form. A pen controlled by two motors moves in the *x* and *y* directions, drawing a picture that is defined in terms of *x* and *y* coordinates.

plotting—The practice of mechanically converting *x*, *y* positional information into a visual pattern, such as artwork.

plotting board—A device that plots one or more variables against one or more other variables.

play effect—In surface-channel charge-coupled devices (CCDs), the tendency for charges to be captured by surface effects, thus resulting in a loss of signal. By continuously introducing a charge into all CCD channels through a diffusion at the beginning of the channel, the

areas that trap charges are filled by the induced charges rather than the signal charges, thus increasing transfer efficiency.

PLT—Abbreviation for power-line transient—one kind of conducted noise, generally caused by switching inductive loads measured on the power line.

plug—1. The part of the two mating halves of a connector that is free to move when not fastened to the mating half. The plug is usually thought of as the male portion of the connector. This is not always the case. The plug may have female contacts if it is the free-to-move member. *See also* connector. 2. Also called plugging and plug reverse. A method of braking a motor by applying partial or full rated voltage in reverse in an attempt to quickly bring the motor to zero speed.

plugboard—In a computer, a removable board having many electric terminals into which connecting cords may be plugged in patterns varying for different programs. To change the program, one wired plugboard is replaced by another.

plugboard computer—A computer that has a punch-card input and output, and to which program instructions are delivered by means of interconnecting patch cords on a removable plugboard.

plug braking—A method of braking an electric vehicle in which the kinetic energy of the vehicle is dissipated as heat, either in a traction motor or a special resistor.

plug-compatible—A term used to indicate when devices may be effectively interchanged without any modifications.

plug connector—An electrical fitting containing male, female, or male and female contacts and constructed so that it can be affixed to the end of a cable, conduit, coaxial line, cord, or wire for convenience in joining with another electrical connector or connectors. It is not designed for mounting on a bulkhead, chassis, or panel.

plug fuse—A fuse of small rating (5 to 30 amperes) with a screw thread like that on an electric lamp base; used in a standard screw receptacle.

pluggable unit—A chassis that can be removed from or inserted into the rest of the equipment by merely plugging in or pulling out a plug.

plugging—*See* plug, 2.

plug-in—1. Any device to which connections can be completed through pins, plugs, jacks, sockets, receptacles, or other ready connectors. 2. A small software program that plugs into a larger application to provide added functionality.

plug-in coil—A coil that can be easily interchanged and used for varying the tuning range of a receiver or transmitter. It is wound around a form often resembling an elongated tube base, with the coil leads connected to pins on the base.

plug-in device—A component or group of components and their circuitry that can be easily installed or removed from the equipment. Electrical connections are made by mating contacts.

plug-in unit—A standard subassembly of components that can be readily plugged into or pulled out of a circuit as a unit.

plug reverse—*See* plug, 2.

Plumbicon—A vidicon with a lead-oxide target; its major advantage is its lack of image retention. It is a tube with the simplicity of a vidicon, and the sensitivity and lag of a glass target image orthicon. The tube is used for live black-and-white and color broadcasting. Trademark of N. V. Philips of Holland.

plumbing—Coaxial lines or waveguides and accessory equipment for transmission of radio-frequency energy.

plume—The hot gaseous material ejected briefly from a highly absorbent material after bombardment by an intense laser pulse. The plume emits broadband white light and is the most prominent feature in most irradiation experiments.

plunger—See piston.

plunger relay—A relay consisting of a movable core or plunger surrounded by a coil. Solenoid action causes the plunger or core to move and, thus, energize the relay whenever current flows through the coil.

plunger-type instrument—A moving-iron instrument for measuring current. It consists of a pointer attached to a plunger inside a coil. The current being measured flows through the coil and pulls the plunger down. How far it goes into the coil depends on the magnitude of the current.

plutonium—A heavy element that undergoes fission when bombarded by neutrons. It is a useful fuel in nuclear reactors. Its symbol is Pu; its atomic number, 94.

pm—Abbreviation for phase modulation or permanent magnet.

pm erasing head—A head that uses the fields of one or more permanent magnets for erasing.

PMOS—1. P-channel metal-oxide semiconductor (MOS) having p-type source and drain regions diffused into an n-type substrate to create a p channel for conduction. 2. MOS devices made on an n-type silicon substrate in which the active carriers are holes (p) flowing between p-type source and drain controls. 3. An MOS (unipolar) transistor in which the working current consists of positive (p) electrical charges. 4. Pertaining to MOS devices made on n-type substrates in which the active carriers flow between p-type source and drain contacts. The n-type channel inverts to p-type at the surface with the application of the proper voltage to the gate terminal. 5. A type of metal-oxide silicon field-effect transistor using holes to conduct current in the semiconductor channel. The channel has a predominantly positive charge.

pm speaker—Abbreviation for permanent-magnet speaker.

pn boundary—The surface where the donor and acceptor concentrations are equal in the transition region between p- and n-type materials.

PNdB—Perceived noise level expressed in decibels. See perceived noise level.

pn diode—A diode that has no intrinsic region and a short storage time. It functions as a normal diode rectifier into the high microwave frequencies. If the diode is given a dc bias that is large compared to the rf signal, it ceases to be a rectifier; thus, it can be used as a reflective microwave switch. It also can be employed as a variable reflective attenuator, except in that operating region for which the bias and rf voltages are comparable and rectification occurs.

pneumatic bellows—A gas-filled bellows sometimes used to provide delay time in plunger-type relays.

pneumatic robot—Programmable machine that usually employs vane motors, and often combines them with cylinders. Both the motors and the cylinders may be standard components that can be serviced on the robot as on any other machine. Each such component represents a degree of freedom, i.e., a way in which the robot can move, either by extending or retracting a cylinder or by rotating a motor-driven joint.

pneumatic speaker—A speaker in which the acoustic output is produced by controlled variation of an air stream.

pn hook transistor—Also called hook transistor or hook collector transistor. A junction transistor that secures increased current amplification by means of an extra pn junction.

pnin—A transistor in which an intrinsic region is between two n-regions.

pnip transistor—A pnp transistor in which a layer of high-purity germanium has been placed between the base and collector to extend the frequency range. When the same process is applied to an npn transistor, the resulting device is called an npin transistor.

pn junction—1. The region of transition between p-type and n-type material in a single semiconductor crystal. 2. The boundary surface between p-type and n-type materials. 3. A relatively abrupt transition between p-type and n-type semiconductor regions within a crystal lattice. Such a junction possesses unique electrical properties, including the ability to conduct substantially in only one direction. Single and multiple pn junctions form the basis for most semiconductor devices. These junctions are fundamental to the performance of switching, rectification, and amplification functions in electronic devices and circuits.

pn junction.

pn-junction laser—See injection laser.

pn-junction luminescence—Discharge that results when a doped semiconductor crystal with a pn junction is charged with a low-voltage direct current. The usual process depends on excitation caused by electrical energy absorption and recombination where release of the absorbed energy occurs.

pnpn diode—Also called four-layer diode. A semiconductor device that may be regarded as a two-transistor structure with two separate emitters feeding a common collector. This combination constitutes a feedback loop that is unstable for loop gains greater than unity. The instability results in a current that increases until ohmic circuit resistances limit the maximum value. This gives rise to a negative-resistance region that may be utilized for switching or for waveform generation.

pnpn transistor—A hook transistor with an n-type base, p-type emitter, and a hook collector. The electrodes are connected to the four end layers of the n- and p-type semiconductor materials.

pnpn-type switch—A bistable semiconductor device made up of three or more junctions, at least one of which is able to switch between reverse and forward voltage polarity within a single quadrant of the anode-to-cathode voltage-current characteristic.

pnp transistor—A transistor consisting of two p-type regions separated by an n-type region. When a small forward bias is applied to the first junction and a large reverse bias to the second junction, the system behaves much like a vacuum-tube triode.

*pnp transistor.*

Pockel's effect—The alternation in the refractive properties of a transparent piezoelectric crystal by the application of an electric field. *See also* modulator crystal.

Pockel's-effect modulation—A phenomenon that occurs when a transparent dielectric is a piezoelectric crystal. The crystal tends to strain whenever an electric field is applied, rotating the plane of polarization of the incident wave. Some 7500 V/m causes a 90° rotation of light.

poïd—The curve traced by the center of a sphere when it rolls or slides over a surface having a sinusoidal profile.

point—Called the binary point in binary notation, and the decimal point in decimal notation. In positional notation, the character or location of an implied symbol that separates the integral part of a number from its fractional part.

point availability—The percent of time an equipment is available for use when an operator requires it.

point-based linearity—Nonlinearity expressed as the deviation from a straight line that passes through a given point or points.

point contact—A pressure contact between a semiconductor body and a metallic point.

point-contact crystal diode—A crystal diode whose rectifying activity is determined by the touching of the crystal to a finely pointed wire surrounded by a material of opposite type.

point-contact diode—1. A diode that consists of a semiconductor against which the end of a fine wire (cat whisker) is pressed. Such a diode has a very low reactance and can be used as a detector or mixer over most of the microwave range. It has a square-law response at low power levels. 2. Device consisting of a metal whisker making pressure contact with the semiconductor chip, normally tungsten for silicon and phosphorus bronze for germanium and gallium arsenide. Point-contact diodes are generally encapsulated in axial lead glass, axial prong ceramic, cartridge-type ceramic, or metal coaxial enclosures. The electrical characteristics of the device are determined by the size, shape, and pressure of the whisker and the thickness and resistivity of the epitaxial layer.

point-contact transistor—A transistor having a base electrode and two or more point-contact electrodes.

point defect—An imperfection caused by the presence of an extra atom or the absence of an atom from its proper place in the crystal.

point effect—The phenomenon whereby a discharge will occur more readily at sharp points than elsewhere on an object or electrode.

pointer—Also called a needle. 1. A slender rod that moves over the scale of a meter. 2. Registers in a CPU that contain memory addresses. *See also* data pointer; program counter.

pointer address—The address of a core-memory location that contains the actual effective address.

pointer register—A register that contains the absolute address of an item of data in its memory. Data can be accessed at this address or relative to it via the pointer register. The value of the pointer register can be updated to access a different block of data, where the data can be one or several bytes.

point impedance—Ratio of the maximum E -field to the maximum H -field observed at a given point in a waveguide or transmission line.

pointing—A method of allowing a nontypist operator to enter data items. A menu of items is displayed on the screen; the operator chooses one by pointing at it with a system device, such as a lightpen, stylus, or even the terminal's cursor.

pointing and flying—The method of navigating through virtual reality when wearing a virtual reality glove by pointing and then "flying" in that indicated direction.

point-junction transistor—A transistor having a base electrode and both point-contact and junction electrodes.

point-of-sale terminal—Abbreviated POS terminal. 1. An intelligent input/output device that is used to capture data in retail stores, i.e., supermarkets or department stores. POS is a term used to indicate that data regarding a sale is entered directly into the computerized system without having to be converted to another form first. 2. Electronic terminal that can serve as a conventional cash register but has the capacity to capture sales data and store or transmit it to a computer.

point-plane rectifier—*See* glow-tube rectifier.

point source—1. A radiation source whose dimensions are small compared with the distance from which it is observed. 2. Radiation source whose maximum dimension is less than 1/10 the distance between source and receiver.

point-to-point—1. Describing communication between two fixed stations. 2. A limited network configuration with communication between two terminal points only, as opposed to multipoint and multidrop.

point-to-point network—A communications network consisting of a single communications link that connects two terminals and is not shared by other terminals.

point-to-point radio communication—Radio communication between two fixed stations.

point-to-point transmission—Direct transmission of data between two points without using an intermediate terminal or computer.

point-to-point wiring—1. A method of forming circuit paths by connecting the various devices, components, modules, etc., with individual pieces of wire or ribbon. May be soldered, welded, or attached by other means. 2. Wiring done in a direct path from one point to another without dressing wiring in parallel runs. Crosstalk is thus reduced. Used for high-speed logic panels.

point transposition—Transposition, usually in an open-wire line, that is executed within a distance comparable to the wire separation, without material distortion of the normal wire configuration outside this distance.

Poisson distribution—A statistical distribution similar to the normal distribution except that the standard deviation is equivalent to the square root of the mean.

Poisson's ratio—The ratio of the lateral strain to the longitudinal strain in a specimen subjected to a longitudinal stress.

polar—Pertaining to, measured from, or having a pole (e.g., the poles of the earth or a magnet).

polar capacitor—A capacitor intended for use with a direct voltage connected according to the polarity indicated on the terminations.

polar circuit—A teletypewriter circuit in which current flows in one direction on a marking impulse and in the opposite direction during a spacing impulse.

polar coordinates—A system of coordinates in which a point is located by its distance and direction (angle) from a fixed point on a reference line (called the polar axis).

polar crystals—Crystals having a lattice composed of alternate positive and negative ions.

polar diagram—A diagram in which the magnitude of quantity is shown by polar coordinates.

Polar diagram.

polar grid—A type of circular grid on which range and azimuth are represented from a central reference point.

polarimetry—The measurement of the rotation of plane of polarization of radiant energy.

polarity—1. A condition by which the direction of current can be determined in an electrical circuit (usually batteries and other direct-voltage sources). 2. Having two opposite charges, one positive and one negative. 3. Having two opposite magnetic poles, one north and the other south. 4. The condition of positiveness or negativeness in an electrical circuit. 5. The positive and negative orientation of a signal or power source. 6. Any condition in which there are two opposing voltage levels or charges, such as positive and negative.

polarity of picture signal—Stated as black negative or black positive. The particular potential state of a portion of the signal representing a dark area of a scene relative to the potential representing a light area.

polarization—1. The process of making light or other radiation vibrate perpendicular to the ray. The vibrations are straight lines, circles, or ellipses—giving plane, circular, or elliptical polarization, respectively. 2. The increased resistance of an electrolytic cell as the potential of an electrode changes during electrolysis. In dry cells, this shortens their useful life. 3. The slight displacement of the positive charge in each atom whenever a dielectric is placed into an electric field. 4. The magnetic orientation of molecules in a piece of iron or other magnetizable material placed in a magnetic field, whereby the tiny internal magnets tend to line up with the magnetic lines of force. 5. The direction of the electric vector in a linearly

polarized wave radiated from an antenna. 6. A mechanical arrangement of inserts and shell configuration (referred to as clocking in some instances) that prohibits the mating of mismatched plugs and receptacles. 7. A technique of eliminating symmetry within a plane so that parts can be engaged in only one way in order to minimize the possibility of electrical and mechanical damage or malfunction. 8. A property of a radiated electromagnetic wave that describes the direction of its electric field.

polarization diversity—A term that designates a method of transmission and reception used to minimize the effects of selective fading of the horizontal and vertical components of a radio signal. It is usually accomplished through the use of separate vertically and horizontally polarized receiving antennas.

polarization-diversity antenna—An antenna in which any of a number of types of polarization can be readily selected. The polarization can be horizontal, vertical, right-hand circular, left-hand circular, or any combination of these four.

polarization-diversity reception—Diversity reception that uses separate vertically and horizontally polarized receiving antennas.

polarization error—In navigation, the error arising from the transmission or reception of radiation having other than the intended polarization for the system.

polarization fading—Fading as the result of changes in the direction of polarization in one or more of the propagation paths of waves arriving at a receiving point. *See also* Faraday effect, 1.

polarization in a dielectric—The slight displacement of the positive charge in each atom whenever a dielectric is placed into an electric field.

polarization index—A practical measure of dielectric absorption expressed numerically as the ratio of the insulation after 10 minutes to the insulation resistance after 1 minute of voltage application.

polarization modulation—A technique in which modulation is produced by changing the direction of polarization of circularly polarized layer energy.

polarization receiving factor—Ratio of the power received by an antenna from a given plane wave of arbitrary polarization to the power received by the same antenna from a plane wave of the same power density and direction of propagation whose state of polarization has been adjusted for the maximum received power.

polarization unit vector (for a field vector)—A complex field vector at one point, divided by the magnitude of the vector.

polarize—1. To cause to be polarized. 2. To arrange mating connectors so that they can be joined in only one way.

polarized capacitor—An electrolytic capacitor with the dielectric film formed adjacent to only one metal electrode. The opposition to the passage of current is then greater in one direction than in the other. The polarity is established for minimum current; operation with reversed polarity can result in damage to the capacitor if excessive current occurs.

polarized double-biased relay—Also called magnetic-latch relay. A relay whose operation depends on the polarity of the energizing current and which is magnetically biased, or latched, in either of two positions. Its coil symbol is usually marked + and DB.

polarized light—Light that has the electric-field vector of all the energy vibrating in the same plane. Looking into the end of a beam of polarized light, one would see the electric-field vectors as parallel or coincident lines.

polarized no-bias relay—A three-position or a center-stable polarized relay. Its coil symbol is usually marked + and NB.

polarized plug—1. A plug so constructed that it may be inserted in its receptacle only in a predetermined position. 2. A multiconductor plug that can be inserted into a jack or receptacle in only one position.

polarized receptacle—A receptacle into which a polarized plug can be inserted only in a predetermined position.

polarized relay—Also called a polar relay. A relay in which the armature movement depends on the direction of the current. Its coil symbol is sometimes marked +.

polarized-vane instrument—See permanent-magnet moving-iron instrument.

polarizer—A substance that, when added to an electrolyte, increases the polarization.

polarizing pin—A pin located on one half of a two-piece connector in such a position that, by mating with an appropriate hole on the other half during assembly of the connector, it will ensure that only related connector halves can be assembled.

polarizing slots—Also called indexing slots. One or more slots placed in the edge of a printed circuit board to accommodate and align certain types of connectors.

polar keying—A form of telegraph signal in which circuit current in one direction is used for marking, and current in the other direction is used for spacing.

polar modulation—A form of amplitude modulation in which the positive excursions of the carrier are modulated by one signal and the negative excursions by another.

polar mount—1. A common mount used with satellite dishes. One axis is aligned with the true north pole so that the satellites in the Clarke belt can be scanned with the movement of only one axis. 2. An antenna mounting and aiming system in which one pivot is positioned only one time and the other (hour axis) is positioned to sweep the satellite arc. Some fine adjustments may be required on the first pivot (declination axis), but this mount is much easier to aim than the azimuth/elevation mount.

polar orbiting satellites—A satellite that orbits over the north and south poles. Since the earth rotates beneath it, the satellite sees a different view on each rotation.

Polar orbiting satellites.

polarotor—A small motor mounted on a dish that rotates the microwave probe (LNA) to receive signals of either horizontal or vertical polarity.

polar radiation pattern—A diagram that shows the relative strength of the radiation from a source in all directions in a given plane.

polar relay—1. A relay containing a permanent magnet that centers the armature. The direction of movement of the armature is governed by the direction of the current. See also polarized relay. 2. A permanent-magnet-core relay that is designed to operate only when current flows in a specified direction. 3. A springless relay built by winding a magnetic core with two equal but opposite windings. The armature stands theoretically in the middle of the two windings. This kind of relay permits the operation of an rty circuit that has current in one direction for marks and in the opposite direction for spaces.

polar response—1. Polar diagram or circular graph that shows the sensitivity of an antenna or microphone or the output from speakers in an angular mode through 360°. 2. The variation of output, at any given frequency, at different angles to the forward axis of symmetry of the speaker. In general, it will be different in horizontal and vertical planes, as well as with frequency.

polar signal—1. A signal whose information is transmitted by means of directional currents. 2. A signal in which the current in the transmission line is reversed in polarity in changing from marking to spacing.

pole—1. One end of a magnet. 2. One electrode of a battery. 3. An output terminal on a switch. 4. An item that controls one path of the circuit. 5. A combination of no and/or nc mating contacts.

pole face—In a relay, the end of the magnetic core nearest the armature.

pole piece—One or more pieces of ferromagnetic material forming one end of a magnet and so shaped that the distribution of the magnetic flux in the adjacent medium is appreciably controlled.

pole shoe—The portion of a field pole facing the armature of the machine. It may be separable from the body of the pole.

poles of a network function—Those real or complex values of p for which the network function is infinite.

pole-type transformer—A transformer suitable for mounting on a pole or similar structure.

police calls—Broadcasts (usually orders) issued by police radio stations.

police connection—The direct link by which an alarm system is connected to an annunciator installed in a police station. Examples of a police connection are an alarm line and a radiocommunications channel.

poling—1. The adjustment of polarity. Specifically, in wire-line practice, it signifies the use of transpositions between transposition sections of open wire or between lengths of cable to cause the residual crosstalk couplings in individual sections or lengths to oppose one another. 2. A step in the production of ceramic piezoelectric bodies that orients the axes of the crystallites in the preferred direction. In general, a process similar to magnetizing ferromagnetic materials.

polishing—1. A mechanical finishing operation conducted upon solid-state substrates to achieve smoothness and desired surface qualities. See also lapping. 2. Act of smoothing ends of fibers to an optically smooth finish, generally using abrasives. Optically smooth surfaces allow maximum transmission of light between fibers at connections and minimum coupling loss.

Polish notation—A system for writing and evaluating logical and arithmetic expressions without the use of parentheses. So called because it was originated by the Polish logician J. Lukasiewicz.

polling — 1. A communications technique that determines when a terminal is ready to send data. The computer continually interrogates all of its attached terminals in a round-robin sequence. A terminal acknowledges the poll when it has data to send. 2. A means of controlling devices on a multipoint line. 3. Controlling communication lines by designating one station as the master. This station then gives control of the line to each of the other stations, in turn, for a predetermined amount of time. 4. A control message sent from a master site to a slave site that serves as an invitation to transmit data to the master site. 5. Scheduling technique for I/O devices, whereby the program interrogates the status of each peripheral in turn and gives service when required. The other essential techniques are interrupts and direct memory access. 6. A process in which a number of peripheral devices, remote stations, or nodes in a computer network are interrogated one at a time to determine if service is required. 7. In data communications, the action of the central system periodically requesting input from multiple terminals on a line by sending a predetermined message (known as a poll sequence) to the terminals.

poll response — See train time.

polycarbonate — An amorphous thermoplastic used in the connector industry and offering high impact strength over a broad temperature range. Polycarbonates are excellent electrical insulators over a wide range of humidity and temperature. They are used as dielectrics in film capacitors. They have a high resistance to creep.

polychromatic radiation — Electromagnetic radiation consisting of two or more frequencies or wavelengths.

polycrystalline cell — A photovoltaic cell made of crystalline semiconductor compounds (two or more different atoms).

polycrystalline ceramic — A ceramic material, such as barium titanate, with a crystalline structure in which all molecules are similarly oriented and regularly arranged. (It may be made piezoelectric by pretreatment with a polarizing electric field.)

polycrystalline material — Material, typically an element like silicon or germanium, made up of many single crystals having a random orientation. The term may be applied to a twin crystal as well as to a heterogeneous growth of many crystals.

polycrystalline structure — The granular structure of crystals that have nonuniform shapes and arrangements.

polyergic — A type of emission in which the groups of energies or velocities are produced simultaneously (e.g., simulated micrometeoroids in varying charge states separated by velocity where accelerated by the same potential).

polyester — Polyethylene glycol terephthalate, the material most often used as a base film for precision magnetic tape. The chief advantages of this material compared to other materials are its stability with respect to humidity and time, its resistance to solvents, and its mechanical strength. It is used as a dielectric in film capacitors.

polyester backing — A plastic-film backing added to magnetic tape to make it stronger and more resistant to changes in humidity.

polyester base — A plastic-film backing for magnetic tape used for special purposes where strength and resistance to temperature and humidity change are important. (Mylar is a Du Pont trade name for their brand of polyester.)

polyester films — A broad category of films that differ in chemical composition, properties, and processibility, but which exhibit very good electrical properties.

polyesters — A class of thermosetting synthetic resins having great strength and good resistance to moisture and chemicals.

polyethylene — Short for polymerized ethylene, a tough white plastic insulator with low moisture absorption. It is often used as a dielectric.

polygon — A closed figure with straight edges; often used as the underlying 3D data structure for shaded 3D systems.

polygraph — Also called a lie detector. A recorder of several signals simultaneously, such as blood pressure, respiratory motion, galvanic skin resistance, etc., commonly used for study of emotional reactions involving deception (lie detection).

polyimide film — A plastic film exhibiting excellent physical and electrical properties over a wide temperature range. Produced from pyromellitic dianhydride and an aromatic diamine, it is used as a printed circuit substrate.

polymer — A compound formed by polymerization that results in the chemical union of monomers or the continued reaction between lower molecular weight polymers.

polynomial — An algebraic expression that contains two or more terms and in which the dependent variable is represented by a linear combination of powers of the independent variable, with the degree of the polynomial determined by the highest power in the expression.

polyphase — Describing an electrical circuit or electrical equipment that uses two or more phases. Polyphase circuits that have two, three, and six phases are common. Thus, a polyphase motor operates from a power line having several phases of alternating current.

polyphase circuit — A group of alternating-current circuits (usually interconnected) that enter (or leave) a delimited region at more than two points of entry. They are intended to be so energized that, in the steady state, the alternating potential differences between them all have exactly equal periods but have differences in phase, and may have differences in waveform.

polyphase motor — An induction motor wound for operation on two- or three-phase alternating current.

polyphase synchronous generator — A generator with its ac circuits so arranged that two or more symmetrical alternating electromotive forces with definite phase relationships to each other are produced at its terminals.

polyphase transformer — A transformer designed for use in polyphase circuits.

polyphase voltages — In an ac electrical system, voltages having a definite phase relationship to each other.

polyplexer — Radar equipment that combines the functions of duplexing and lobe switching.

polypropylene — A thermoplastic with good electrical characteristics, high tensile strength, and resistance to heat. It is used as a dielectric in film capacitors.

polyrod antenna — An end-fire dielectric microwave antenna made of tapered polystyrene rods.

polysilicon — A multicrystalline form of silicon used in silicon-gate MOS technology that is electrically conductive and optically transparent. It is commonly used to form electrodes of solid-state imaging devices.

polystyrene — A clear thermoplastic material having excellent dielectric properties, especially at ultrahigh frequencies.

polystyrene capacitor — A low-loss precision capacitor with a polystyrene dielectric.

polysulfones—Plastics that are transparent and have high dimensional stability and high heat-deflection temperature. They are tough and strong and have excellent dimensional stability and electrical properties.

polyvinyl chloride—Abbreviated PVC. A general-purpose thermoplastic used for insulations and jackets on components, wire, and cable.

pony circuit—A local, on-base circuit that does not have direct entry into a relay network.

pool cathode—A cathode at which the principal source of electron emission is a cathode spot on a metallic-pool electrode.

pool tube—A gas tube with a pool cathode.

popcorn noise—Also called burst noise. 1. So named for the audible characteristic, popcorn noise is randomly occurring random-amplitude noise, lasting from a few microseconds to several seconds. A type of noise generally associated with operational amplifiers. When popcorn noise is present, it does not occur in all devices made by a given process or even in all devices on the same wafer. It becomes worse at low temperatures, and it disappears above some threshold temperature. 2. An undesired source of interference associated with semiconductor devices that usually exceeds the background noise by at least a factor of 2 and occurs randomly at very long intervals. Popcorn noise is characterized by pulses of current in a semiconductor device operating in an electrical circuit. It can be observed by placing a high-value resistor in the base circuit of a transistor and observing the amplified noise signal present at the collector.

Pope cell—See sulfonated polystyrene sensor.

pop filter—1. A cloth, foam, or similar shield placed over a microphone to prevent popping sounds resulting from sudden bursts of breath. 2. A filter that attenuates low frequencies where the popping sounds exist. Typically, a high-pass filter with its cutoff at approximately 70 Hz to 100 Hz. 3. See blast filter.

POPI—Post Office Position Indicator. A British long-distance navigational system for providing bearing information. It is a continuous-wave, low-frequency system in which the phase difference between sequential transmissions on a single frequency is measured.

pops—A form of record noise that usually results from disc imperfections and the ever-present electrostatic charge (with its attendant crackling sounds) on the disc.

population—Sometimes called universe. The entire group of items being studied, from which samples are drawn..

population inversion—1. A nonequilibrium condition that exists when there are more atoms in the excited state than in the ground state. Atoms return to the lower-energy level, and release energy and emit photons. 2. A condition in a stimulated material, such as a semiconductor, in which the upper energy level of two possible electronic energy levels in a given atom, distribution of atoms, molecule, or distribution of molecules has a higher probability (usually only slightly higher but nevertheless higher) of being occupied by an electron. When population inversion occurs, the probability of downward energy transitions giving rise to radiation is greater than the probability of upward energy transitions. This thus brings about stimulated emission, i.e., laser action. 3. The condition in which there are more atomic systems in the upper of two energy levels than in the lower, so stimulated emission will predominate over stimulated absorption. 4. In the context of semiconductors, any situation in which the normal majority/minority carrier ratio of an impurity semiconductor region is disturbed, to a degree that the nominal minority carriers are actually present in larger numbers than the nominal majority carriers. 5. A redistribution of energy levels in a population of elements such

that instead of having more atoms with lower energy level electrons there are fewer atoms with higher energy level electrons, i.e., an increase in the total number of electrons in the higher excited states occurs at the expense of the energy in the electrons in the ground or lower state and at the expense of the resonant energy source, i.e., the pump. This is not an equilibrium condition. The generation of population inversion is caused by pumping.

porcelain—A glazed ceramic insulating material made from clay, quartz, and feldspar.

porcelain capacitor—A fixed electrostatic capacitor whose dielectric is a high grade of porcelain molecularly fused to alternate layers of fine silver electrodes so as to form a monolithic capacitor.

porcelainize—To coat and fire a metal with glass material, forming a hybrid circuit substrate.

port—1. A point of access into a computer (such as the serial and parallel ports on the back of most PCs), a network, or other electronic system; the physical or electrical interface through which one gains access; the interface between a process and a communications or transmission facility. 2. The hardware that permits data to enter or exit a computer, network node, or communications device. See also communications port. 3. A place of access to a system or circuit. Through it, energy can be selectively supplied or withdrawn or measurements can be made. Examples are the port in a waveguide or in a base-reflex speaker enclosure. 4. A fluid connection to the servovalve (e.g., supply port, return port, control port). 5. An external opening of an internal passage. 6. The physical circuit that interfaces a computer to a peripheral, and the numerical address the computer uses in communicating through it. 7. An opening in a speaker enclosure, permitting the bass radiation from the back of the woofer cone to be combined with its forward radiation to enhance the total response. 8. An input/output channel, including the physical connector and control logic, to interface a peripheral device to a mainframe. 9. A set of lines for internal and external communication with a computer. 10. An outlet in a processor where a peripheral plugs in, in equipment in which the peripheral is compatible with the processor. 11. The gateway that connects the computer to its outside world. 12. To convert software to run in a different computer environment.

portable data medium—A data medium intended to be transportable easily and independently of the mechanism used in interpreting it.

portable duress sensor—A device carried on a person that may be activated in an emergency to send an alarm signal to a monitoring station.

portable intrusion sensor—A sensor that can be installed quickly and that does not require the installation of dedicated wiring for the transmission of its alarm signal.

portable operation—Radiocommunication conducted from a specific geographical location other than that shown on the station license.

portable recorder—A sound and/or video recorder designed for easy mobility, but which may require connection to a 120-volt ac supply for operation. Also applied to battery-powered recorders that do not require external power for operation.

portable standard meter—A portable meter used principally as a standard for testing other meters.

portable transmitter—A transmitter that can be readily carried on one's person and operated while in motion (e.g., walkie-talkies, Handie-Talkies, and similar personal transmitters). See also transportable transmitter.

portamento—The continuous change of a tone from one pitch to another. See also glissando.

port selector—A switching device that extends the capability of a computer to handle more data traffic without additional ports. It eliminates dedicated line-to-port interfacing, so fewer ports can handle more data lines.

pos—Abbreviation for positive.

posistor—A thermally sensitive resistor that has a positive temperature characteristic of resistance.

position—1. The location of an object with respect to a specific reference point or points. 2. In a string, a location that can be occupied by a character or bit and that can be identified by a serial number.

positional crosstalk—In a multibeam cathode-ray tube, the deviation of an electron beam from its path under the influence of another electron beam within the tube.

positional notation—One of the schemes for representing numbers. It is characterized by the arrangement of digits in sequence, with successive digits forming coefficients of successive powers of an integer called the base of the number system.

position-changing mechanism—The mechanism used to move a removable circuit-breaker unit to and from the connected, disconnected, and test positions.

position control system—A discrete or point-to-point control in which the controlled motion is used as a means of arriving at a given end point without path control during the movement between end points.

position dialing—Dialing over the regular position cord circuits by means of a relay circuit controlled by a dial of the regular cord circuits.

position feedback—A feedback signal that is proportional to the position or deflection of some object.

position-independent code—Abbreviated PIC. Machine-coded programs using only relative addressing, permitting the program to reside in any portion of system memory.

position of effective short—The distance between a specified reference plane and the apparent location of the short circuit of a fixed switching tube in its mount.

position sensor—A device that measures position and converts the measurement into a form convenient for transmission as a feedback signal.

position-type telemeter—*See* ratio-type telemeter.

positive—Abbreviated pos 1. Any point to which electrons are attracted—as opposed to negative, from where they come. 2. An artwork, artwork master, or production master in which the intended conductive pattern is opaque to light, and the areas intended to be free from conductive material are transparent.

positive bias—The condition in which the control grid of a vacuum tube is more positive than the cathode.

positive charge—An electrical charge with fewer electrons than normal.

positive column—The luminous glow, often striated, between the Faraday dark space and the anode in a glow-discharge, cold-cathode tube.

positive electricity—The electricity that predominates in a glass body after it has been electrified by rubbing with silk. *See* positive charge.

positive electrode—The conductor that is connected to the positive terminal of a primary cell and serves as the anode when the cell is discharging. Electrons flow to it through the external circuit.

positive electron—*See* positron.

positive feedback—1. The process by which the amplification is increased by having part of the power in the output circuit returned to the input circuit in order to reinforce the input power. 2. Recycling of a signal that is in phase with the input to increase amplification. Used in

port selector — positive temperature coefficient

digital circuits to standardize the waveforms in spite of any anomalies in the input. *See also* regeneration, 1.

positive ghost—A television ghost-signal display with the same tonal variations as those of the image.

positive-going—Increasing toward a positive direction (e.g., a current or waveform).

positive grid—A grid with a more positive potential than the cathode in a vacuum tube.

positive-grid multivibrator—A multivibrator that has one or more grids connected to the plate-voltage supply, usually through a large resistance.

positive-grid oscillator—*See* retarding-field oscillator.

positive-grid oscillator tube—Also called a Barkhausen tube. An oscillating triode in which the grid has a more positive quiescent voltage than either of the other electrodes.

positive ground—The positive battery terminal of a vehicle is connected to the body and frame.

positive-intrinsic-negative photodiode coupler—A coupling device that enables the coupling of light energy from an optical fiber or cable onto the photosensitive surface of a positive-intrinsic-negative (pin) diode of a photon detector (photodetector) at the receiving end of an optical-fiber data link. The coupler may be only a fiber pigtail epoxied to the photodiode.

positive ion—An atom that has lost one or more electrons and, thus, has an excess of protons, giving it a positive charge.

positive-ion emission—Thermionic emission of positive particles from the cathode of a vacuum tube. They either are made up of ions from the metal in the cathode or are due to some impurity in it.

positive-ion sheath—A collection of positive ions on the control grid of a gas-filled triode tube. If too high a negative bias is applied to the grid, this positive sheath will block the plate current.

positive light modulation—Modulation in which the transmitted power increases as the light intensity does, and vice versa.

positive logic—A form of logic in which the more positive logic level represents 1 and the more negative level represents 0.

positive magnetostriction—Magnetostriction in which a material expands whenever a magnetic field is applied.

positive modulation—Also called positive picture modulation. In an AM television system, modulation in which the brightness increases as the transmitted power does, and vice versa.

positive phase-sequence relay—A relay that is energized by the positive phase-sequence component of the current, voltage, or power of a circuit.

positive picture modulation—*See* positive modulation.

positive picture phase—1. The condition in which the picture-signal voltage goes positive above the zero level whenever a positive scene or picture increases in brilliance. 2. Positioning of the composite video signal so that the maximum point of the sync pulses is at zero voltage. The brightest illumination is caused by the most positive voltages.

positive plate—1. A hollow lead grid filled with active material and connected to the positive terminal of a storage battery. When the battery is discharging, electrons flow toward it through the external circuit. 2. In a charged capacitor, the plate that has fewer electrons.

positive ray—*See* canal ray.

positive temperature coefficient—The condition whereby the resistance, capacitance, length, or other

characteristic of a substance increases as the temperature does.

positive terminal—In a battery or other voltage source, the terminal toward which electrons flow through the external circuit from the negative terminal.

positive transmission—Transmission of television signals in such a way that the transmitted power increases whenever the initial light intensity does.

positive-true logic—A logic system in which the voltage representing a logical 1 has a higher or more positive value than that representing a logical 0.

positron—Fundamental particle equal in mass and energy to an electron, but having a positive charge. It has a very short life, being usually lost in the formation of a photon by combination with an electron. It occurs in the radiations from a few radioactive isotopes.

post—1. In a computer, to place a unit of information in a record. 2. To submit a message in a newsgroup or other online forum.

postaccelerating electrode—*See* intensifier electrode.

postacceleration—Also called postdeflection acceleration. Acceleration of the beam electrons in a tube after they have been deflected.

postconversion bandwidth—In a telemetry receiver, the bandwidth presented to the detector.

postcuring—Heat aging of a film circuit after firing to stabilize the resistor values through stress relieving.

postdeflection accelerating electrode—*See* intensifier electrode.

postdeflection acceleration—*See* postacceleration.

postedit—In a computer, to edit output data resulting from a previous computation.

postemphasis—*See* deemphasis.

postequalization—*See* deemphasis.

POS terminal—*See* point-of-sale terminal.

postfiring—Refiring of a film circuit after having gone through the firing cycle. Sometimes used to change the values of the already fired resistors.

postmortem—A diagnostic computer routine for locating a malfunction in the computer or an error in coding a problem. Should a problem tape come to a standstill, the computer will print out—either automatically or when called for—any information concerning the contents of all or part of the registers in the computer.

post processor—A software subsystem that converts stimulus and response information obtained from a simulator into the machine language of a particular automatic test equipment.

postregulator—A circuit that performs the functions of reference, comparison, and control in power supplies. So called because it follows the transformer, rectifier, and (usually) the ripple filter.

pot—1. Short for potentiometer. 2. A solder pot. 3. To embed a component in a liquid resin within a casing that becomes part of the product.

potassium—An alkali metal having photosensitive characteristics, especially to blue light. It is used on the cathodes of phototubes whenever maximum response to blue light is desired.

pot core—A magnetic structure consisting of a rod and a sleeve arranged so that the rod fits inside a coil and the sleeve fits around the coil. The sleeve and rod are connected at one end by a plate. The open end (opposite the plate) is usually, but not necessarily, ground so that two pot cores or a pot core and a separate plate can be put together around a suitable coil to form a low-reluctance magnetic path and/or shield for the coil.

potential—1. The difference in voltage between two points of a circuit. Frequently one point is assumed

to be ground, which has zero potential. 2. In general, the electrical voltage difference between two bodies. When bodies of different potentials are brought into communication, a current is set up between them.

potential barrier—A semiconductor region through which electric charges attempting to pass will encounter opposition and may be turned back.

potential coil—The shunt coil in a measuring instrument or other device having series and shunt coils—i.e., the coil connected across the circuit and affected by changes in voltage.

potential difference—1. A voltage existing between two points (e.g., the voltage drop across an impedance, from one end to another). 2. The voltage that can be measured between any two points in a circuit. 3. The algebraic difference between the voltages at two points in an electrical circuit.

potential divider—*See* voltage divider.

potential drop—The difference in potential between the two ends of a resistance with a current through it.

potential energy—Energy due to the position of one body with respect to another or to the relative parts of the same body.

potential galvanometer—A galvanometer with such a high resistance that it takes practically no current. It has been replaced by the vacuum-tube voltmeter.

potential gradient—1. The rate of change of potential with distance. Units such as volts per meter or kilovolts per centimeter may be used. 2. Voltage gradient due to the diffusion of holes and electrons across the space charge region.

potential transformer—Also called a voltage transformer. An instrument transformer whose primary winding is connected in parallel with the circuit whose voltage is to be measured or controlled.

potential wells—A voltage placed on MIS capacitor electrodes causes a voltage gradient zone to be formed under the electrode so as to collect minority carriers.

potentiometer—1. A resistor provided with a tap that can be moved along it in such a way as to put the tap effectively at the junction of two resistors whose sum is the total resistance, the ratio of the two effective resistors being a function of the position of the tap. 2. A measuring instrument in which a potentiometer is used as a voltage divider in order to provide a known voltage that can be balanced against an unknown voltage. 3. A variable voltage divider. A resistor that has a variable contact arm so that a portion of the potential applied between its ends may be selected. 4. A variable voltage divider used for measuring an unknown electromotive force or potential difference by balancing it, in whole or in part, by a known potential difference. 5. An instrument used to measure or compare voltages.

Potentiometer.

potentiometer circuit—A network arranged so that when two or more electromotive forces (or potential differences) are present in as many branches, the response of a suitable detecting device in any branch can be made zero by adjusting the electrical constants of the network.

potentiometer recorder—A null-balance type of recorder using a servo-operated voltage-balancing device; the sliding contact of a precision measuring potentiometer is adjusted automatically by a servomechanism so that the difference in voltage of the circuit becomes zero. Main feature is high sensitivity.

potentiometric transducer—A transducer in which displacement of a force-summing member is transmitted to the slider in a potentiometer, thus changing the ratio of output resistance to total resistance. Transduction is accomplished by changing the ratios of a voltage divider.

potentiometric transduction—The conversion of the measurand into a change in the position of a contact on a resistance element across which excitation is applied, the output usually being given as a voltage ratio.

pothead—An insulator for making a sealed joint between an underground cable and overhead line.

Potier diagram—A vector diagram showing the voltage and current relationships in an ac generator.

pot life—Also called working life. 1. The period after the addition of a catalyst to a potting compound during which the potting operation must be completed. 2. The time period during which a compound remains suitable for the intended use after compounding ingredients, such as solvents or catalysts, have been added.

potted circuit—A circuit that has been encapsulated in a nonconductive material.

potted line—A pulse-forming network immersed in oil and enclosed in a metal container.

Potter oscillator—A cathode-coupled multivibrator.

potting—1. An embedding process for parts that are assembled in a container or can into which the insulating material is poured, with the container remaining an integral part as the outer surface of the finished unit. 2. Sealing of a component (e.g., the cable end of a multiple-contact connector) with a plastic compound or material to exclude moisture, prevent short circuits, and provide strain relief. 3. A process of embedding a part or assembly by complete immersion in the potting compound. A container, can, or shell used as a mold is retained as an integral part of the finished product. Usually refers to protective encasements of greater than 100 mils (2.54 mm) thickness.

potting compound—A sealing material used to fill the case or enclosure in which a component is contained.

powdered-iron core—A core consisting of fine particles of magnetic material mixed with a suitable bonding material and pressed into shape.

power—1. The energy dissipated in an electrical or electronic circuit or component that is conducting either ac or dc. 2. Electrical energy developed to do work, such as the voltage from an amplifier used to drive a speaker. Also acoustical energy or sound pressure developed in a room by a speaker. 3. Rate of doing work. Some units of power are the foot-pound per second, or (in the cgs system) 1 erg/sec, the watt (joule/second), and the kilowatt.

power amplification—See power gain, 1.

power amplifier—1. An amplifier intended for driving one or more speakers or other transducers. 2. The final stage in a multistage amplifier circuit, designed to give power to the load, rather than to be used mainly as a voltage amplifier. 3. A fluidic device that causes a change in output power following a change of sufficient

magnitude in control power. 4. An amplifier driven by a relatively low voltage, low-power signal (of the order of 0.1 milliwatt or less) that delivers a substantial power output to low-impedance speaker loads. Typical power outputs may range from a few watts to several hundred watts, into impedances in the range of 2 to 16 ohms. The term power amplifier is commonly used to distinguish an amplifier that does not handle source signals directly and does not have volume or tone control functions. 5. A device that causes a change in output power following a change in control power. 6. An amplifier that can deliver a relatively large current and that can often operate from fairly high voltages. Power amplifiers are widely used in audio, but can also be used to drive servomotors and the like.

power amplifier input sensitivity—The input that will drive an amplifier to its maximum rated output power. Usually measured in dBm, dBV, or volts.

power-amplifier stage—1. An audio-frequency amplifier stage capable of handling considerable audio-frequency power without distortion. 2. A radio-frequency amplifier stage used in a transmitter primarily to increase the power of the carrier signal.

power attenuation—See power loss, 1.

power bandwidth—The range of audio frequencies over which an amplifier can produce half its rated power without exceeding its rated distortion. It is determined by using a measurement procedure standardized by the Institute of High Fidelity (IHF). This specification indicates how much power is available at the critical high and low frequencies. The wider the power bandwidth, the better the amplifier.

power (temperature-rise) coefficient—The maximum rise in hot-spot temperature of a resistor above ambient, per watt of dissipation, assuming free-air convection and negligible loss of heat through the leads, after thermal equilibrium has been reached, usually expressed in degrees Celsius per watt.

power conditioning—The process of maintaining uniform voltage on a power line.

power connection—British term used for the constant horsepower connection in a multispeed motor.

power consumption—The maximum wattage used by a device within its operating range during steady-state signal conditions.

power cord—Flexible, insulated cable used in such applications as supplying line power to power tools and electronic equipment.

power density—1. The radiated field strength set up by a radiating source, expressed in microvolts per meter or in dB above 1 μ V/m. 2. Power in a band per hertz, or the total power in a band of frequencies divided by the bandwidth in hertz. 3. The power output of a battery, expressed in watts, per unit weight of the battery.

power derating—Use of computed curves to determine the correct power rating of a device or component to be used above its reference ambient temperature.

power detection—Detection in which the power output of the detector is used for supplying a substantial amount of power directly to a device such as a speaker or recorder.

power detector—A vacuum tube detector operating with such a high plate voltage that strong input signals can be handled without appreciable distortion.

power dissipation—1. The dispersion of the heat generated within a device or component when a current flows through it. This is accomplished by convection to the air, radiation to the surroundings, or conduction. 2. The supply power consumed by a logic circuit operating with a 50-percent duty cycle (equal times in the logical 0 and logical 1 states).

power dissipation rating—The maximum average power that can be continuously dissipated under stated temperature conditions.

power divider—1. A device that provides a desired distribution of power at a branch point in a waveguide system. 2. A passive resistive network that equally divides power applied to the input port between any particular number of output ports without substantially affecting the phase relationship or causing distortion.

power driver—An amplifier with two outputs that can be used to drive a pair of complementary power transistors. The output power available from these transistors can be very high. An ordinary operational amplifier is not very suitable for use as a power driver, since only one output is available and this cannot be used easily to drive the power transistors, which require a bias difference between their input for low crossover distortion.

power dump—Also called dump. The removal of all power either accidentally or intentionally.

power factor—1. Ratio of the actual power of an alternating or pulsating current, as measured by a wattmeter, to the apparent power, as indicated by an ammeter and voltmeter. 2. Ratio of resistance to impedance; therefore, a measure of the loss in an inductor, capacitor, or insulator. 3. The cosine of the phase angle between the voltage applied to a load and the current passing through it. (Sometimes the cosine is multiplied by 100 and expressed as a percentage.) 4. The ratio of actual power being used in a circuit, expressed in watts or kilowatts, to the power that is apparently being drawn from the line, expressed in voltamperes or kilovoltamperes. Actual power is working, or real or true, power used to produce heat or work. Apparent power is the product of volts times amperes, and may or may not be more than the actual power. When the two values are equal, their ratio is 1:1, or 1.0, or 100 percent. This is the highest power factor (unity) that can be obtained.

power-factor correction—Adding capacitors to an inductive circuit in order to increase the power factor by making the total current more nearly in phase with the applied voltage.

power-factor meter—A direct-reading instrument for measuring power factor. Its scale is graduated directly in power factor.

power-factor regulator—A regulator that maintains the power factor of a line or apparatus at a predetermined value, or varies it according to a predetermined plan.

power-factor relay—A device that operates when the power factor in an ac circuit becomes above or below a predetermined value.

power-fail circuit—A logic circuit that protects an operating program if primary power fails. A typical power-fail circuit informs the computer when power failure is imminent, initiating a routine that saves all volatile data. After power has been restored, the circuit initiates a routine that restores the data and restarts computer operation.

power fallback—Reduction of the power input to a power supply under fault conditions to less than the full rate input power under normal conditions.

power frequency—The frequency at which electric power is generated and distributed. Throughout most of the United States, this frequency is 60 Hz.

powerful—Usually refers either to a computer with a lot of memory or a lot of processing speed (a personal computer with 256 K RAM is powerful) or to a program with an unusual versatility (a spreadsheet is a powerful business tool).

power gain—Abbreviated pg. Also called power amplification. 1. The ratio of the signal power developed

at the output(s) of a device to the signal power applied at the input(s). 2. Of an antenna in a given direction, 4 π times the ratio of the radiation intensity to the total power delivered to the antenna. (The term is also applied to receiving antennas.)

power ground—1. The ground between units that is part of the circuit for the main source of power to or from these units. 2. The potential of the terminal or circuit point to which the output of a power supply and often an amplifier output load is returned (i.e., power-supply “zero”).

power-handling capability—1. A measure of the maximum power input a speaker can absorb without damage or unreasonable distortion. In speaker systems the power-handling capacity will vary depending on the frequency and length of time the signal is applied. 2. The maximum power rating of a component, which determines how much current can be passed safely without adverse effects.

power IC—A monolithic integrated circuit that combines, on the same chip, signal-level digital logic and analog functions, for signal processing or interface, with one or more output power devices. The power IC is essentially an extension of the prevalent small-signal integrated circuit concept. A power IC is more specifically defined as a single-chip circuit that operates at 2 or more amperes and/or 2 or more watts.

power keys—A computer interface in which certain simple key-stroke combinations perform the same function as opening a pull-down menu and then selecting an entry.

power level—At any point in a transmission system, the difference between the measure of the steady-state power at that point and the measure of an arbitrarily specified amount of power chosen as a reference.

power-level indicator—An ac voltmeter calibrated to read audio power level.

power line—Two or more wires conducting electric power from one location to another.

power-line transient—See PLT.

power loss—Also called power attenuation. 1. Ratio of the power absorbed by the input circuit of a transducer to the power delivered to a specified load under specified operating conditions. 2. Also called watt loss. In the circuit of an instrument for measuring current or voltage, the active power at its terminals for nominal full-scale indication. For other instruments, for example, wattmeters, the power loss is expressed at a stated value of current or voltage.

power modulation factor—Ratio of the maximum positive departure of the envelope of an amplitude-modulation wave from its average value to its average value. This rating is used when the modulating signal wave has unequal positive and negative peaks.

power output—1. The power in watts delivered by a power amplifier to a load such as a speaker. 2. Amplifier power measured with all channels operating, after a standard preconditioning period that brings amplifier components to their maximum working temperature.

power output (continuous watts)—In an amplifier, the power output at a total maximum harmonic distortion of 0.5 percent with a pure-tone (sine-wave) input.

power pack—A unit for converting power from an alternating- or direct-current supply into alternating- or direct-current power at voltages suitable for supplying the proper operating power to an electronic device.

power programmer—A device for controlling the output power of a radar automatically as a function of the target range.

power rating—The maximum power that can be dissipated in a component or device for a specified period.

power ratio—Ratio of the power output to the power input of a device. Usually expressed as the number of decibels loss or gain.

power relay—1. A relay that functions at a predetermined value of power. It may be an overpower relay, an underpower relay, or a combination of both. 2. General-purpose relay with high ratings, generally 10 to 20 amperes or greater. Some relays in this category may be open frame in that they are not protected with individual dust covers; they are covered with a common dust cover in the end-use equipment.

power response—The frequency-response capabilities of an amplifier running at or near its full rated power.

power semiconductor device—Solid-state device capable of handling 1 watt of power or more at room temperature. Included are rectifiers, transistors, and thyristors.

power spectral density function—A measure of the power distribution of a signal with respect to frequency.

power-speed product—The product of a semiconductor device's propagation delay and its power dissipation.

power supply—1. A unit that supplies electrical power to another unit. Generally, a circuit that accepts alternating current and converts it into direct current that is regulated precisely enough to drive electronic circuits and that maintains a constant voltage output within limits. For most electronics, the source of power is line voltage (117 V to 220 V, 60 Hz). Most electronic circuits today require low-voltage dc, typically 12 V or less. At present there are three different design approaches to providing this regulated dc: the series or linear regulated supply, the ferroresonant supply, and the switching regulated supply. 2. Energy source that provides power for operating electronic apparatus.

power-supply rejection ratio—The ratio of the change in input offset voltage of an operational amplifier to the change in power-supply voltage that causes it.

power switch—Often called an on-off switch. The switch that connects or disconnects a radio receiver, transmitter, or other equipment from its power line.

power switchboard—Part of a switch gear consisting of a panel or panels on which the switching-control, measuring, protective, and regulatory equipment is mounted. The panel or panel supports also may carry the main switching and interrupting devices and their connections.

power transformer—A transformer used for raising or lowering the supply voltage to the various values required by vacuum-tube plate, heater, and bias circuits.

power transistor—1. A transistor designed to handle large currents and safely dissipate large amounts of power. 2. A transistor that can dissipate more than

1 watt of power. General-purpose types are used for low-frequency service (below 3 MHz) as amplifiers, switches, or current regulators. Rf types are used to amplify high-frequency signals (above 3 MHz) that reach up to VHF, UHF, and microwave regions. 3. A transistor that handles power levels of about 0.25 watt and above. Units handling about 0.25 to 10 watts are called medium-power transistors, whereas high-power transistors are those handling above 10 watts.

power tube—An electron tube designed to handle more current and power than a voltage-amplifier tube.

power winding—A saturable-reactor winding to which the power to be controlled is supplied. Commonly, the output and power are furnished by the same winding, then termed the output winding.

Poynting's law—The transfer of energy can be expressed as the product of the values of the magnetic field and of the components of the electric field that are perpendicular to the magnetic field, and the flow of energy at any point is perpendicular to both fields.

Poynting's theorem—The rate of flow of electromagnetic energy into or out of a closed region is at any instant proportional to the surface integral of the vector product of the electric and magnetic intensities.

Poynting's vector—1. The vector product of the electric and magnetic intensities at one point and at a given instant in a wave. 2. In remote sensing technology, represents the intensity of energy flow in the direction of wave propagation.

PPI—Abbreviation for plan-position indicator.

PPI repeater—Also called remote plan-position indicator. A unit that repeats a plan-position indicator at a place remote from the radar console.

PPI scope—A cathode-ray oscilloscope arranged to present a PPI display.

pp junction—A region of transition between two regions having different properties in a p-type semiconducting material.

p+ region—The region created by diffusing into a silicon crystal a group III element, which creates a deficiency of electrons or an excess of holes.

p+ semiconductor—A p-type semiconductor with an extremely large excess mobile hole concentration.

p+ type material—Heavily doped p-type material, formed by introducing acceptor impurities into a silicon substrate. Conduction takes place by the movement of the holes.

PPM—Abbreviation for pulse-position modulation.

ppm—Abbreviation for parts per million.

PPM/AM—Amplitude modulation of a carrier by pulses that are position modulated by data.

pps—Abbreviation for pulses per second.

practical system of electrical units—A system in which the units are multiples or submultiples of the units of the centimeter-gram-second electromagnetic system.

praetersonic—The higher region of the sonic spectrum.

praetersonics—The propagation and signal processing of acoustic waves in solids at frequencies that extend into the microwave region.

preamplifier—1. An amplifier that primarily raises the output of a low-level source so that the signal may be further processed without appreciable degradation in the signal-to-noise ratio. A preamplifier may also include provision for equalizing and/or mixing. 2. Also known as control amplifier or control center. A switching, amplification, and equalization component designed to select input signals, amplify them by amounts from 0 to 60 dB, and deliver an output voltage compatible with the input requirements of a power amplifier.

Power transistor.

preburning — Stabilizing vacuum tubes by operating their heaters continuously for a given number of hours. Cathode current may be drawn and the tubes vibrated at the same time.

precession — The effect resulting when a torque is applied to a rotating body, such as a gyroscope, causing it to wobble. The wobbling frequency is determined by the gravitational field strength and the mass of the body.

Precession of a gyroscope.

precious metal — One of the relatively scarce and valuable metals: gold, silver, and the platinum group metals.

precipitation attenuation — A reduction in radio energy as it passes through a volume of the atmosphere that contains precipitation. Part of the energy loss results from scattering, and part results from absorption.

precipitation noise — Noise generated in an antenna circuit, generally in the form of a relaxation oscillation, caused by the periodic discharge of the antenna or conductors in the vicinity of the antenna into the atmosphere.

precipitation static — A type of interference experienced in a receiver during snow, rain, and dust storms. Often caused by the impact of dust particles against the antenna or the creation of induction fields by nearby corona discharges.

precipitator — Sometimes called a precipitron. An apparatus for removing small particles of smoke, dust, oil, mist, etc. from the air by electrostatic precipitation.

precipitron — See precipitator

precise (or precision) measurement — Careful measurement under controlled conditions that can be repeated again and again with similar results. It also means that small differences can be detected and measured with confidence. Precision is related, then, to confidence in successive measurements with the same equipment and operating conditions.

precision — 1. The quality of being sharply or exactly defined—i.e., the number of distinguishable alternatives from which a representation was selected. This is sometimes indicated by the number of significant digits the representation contains. See also accuracy. 2. Also called reproducibility or repeatability. The degree with which repeated measurements of a given quantity agree when obtained by the same method and under the same conditions.

precision approach radar — Abbreviated PAR. 1. A rapid-scanning airport radar system so located that aircraft on approach to the runway are presented on the display in terms of linear deviation from a desired glide path and in terms of distance from the point of touchdown on the runway. 2. Radar used by traffic controllers in a ground-controlled approach to talk down a pilot on final approach.

precision-balanced hybrid circuit — A circuit for interconnection of a four-wire telephone circuit with a particular two-wire circuit, in which the impedance of the balancing network is adjusted so that a relatively high degree of balance is obtained.

precision comparator — A high-gain amplifier circuit whose output changes decisively between two definite levels whenever the sum of the input voltages change sign.

precision device — A device that operates within prescribed limits and will consistently repeat operations within those limits.

precision gate — A circuit that may be switched from closed to open circuit or vice versa without error (time, bias, impedance) in response to a command signal (voltage or current).

precision limit switches — Usually snap-acting switches that require a very small known movement to actuate. Many machines depend on the accuracy and repeatability of the precision limit switch. (Travel of 0.001 inch, or 25.4 μm , is possible.) The force needed to close a limit switch is varied from fractions of an ounce (a few grams) to pounds.

precision net — In a four-wire terminating set or similar device employing a hybrid coil, an artificial line designed and adjusted to provide an accurate balance for the loop and subscriber's set or line impedance.

precision potentiometer — A mechanical electrical transducer dependent upon the relative position of a moving contact (wiper) and a resistance element for its operation. It delivers a voltage output that is some specified function of the applied voltage and shaft position, to a high degree of accuracy.

Precision potentiometer.

precision snap-acting switch — An electromechanical switch having predetermined and accurately controlled characteristics and having a spring-loaded quick make-and-break contact action.

precision sweep — A delayed expanded radar sweep for high resolution and range accuracy.

preconduction current — The low value of plate current in a thyatron or other grid-controlled gas tube prior to conduction.

precursor — Also called undershoot. The initial transient response to a unidirectional change in input. It precedes the main transition and is opposite in sense.

predefined process — A named process that consists of one or more operation or program steps that are specified in another part of a routine.

predetection combining — A method for producing an optimum signal from multiple receivers in a diversity reception.

predetection recording — The recording of telemetry receiver intermediate-frequency signals.

predetermined counter — A device that automatically stops an instrument to which it is attached when a preset limit is reached.

predictive control — A type of computer control that allows a digital computer to include a dynamic control loop for repetitive comparison of pertinent factors.

predissociation — The dissociation that occurs in a molecule that has absorbed energy before it has had an opportunity to lose energy by radiation.

predistortion — *See* preemphasis.

pre-Dolbyed tape — A prerecorded tape with Dolby compression added for low-noise playback in the home via a Dolby B stretcher.

preemphasis — Also called preequilization or predistortion. 1. In a system, a process designed to emphasize the magnitude of some of the frequency components. Preemphasis is applied at the transmitting end (with deemphasis at the receiving end) in order to improve the signal-to-noise ratio. 2. In recording, an arbitrary change in the frequency response from its basic response (e.g., constant velocity or amplitude) in order to improve the signal-to-noise ratio or to reduce distortion. *See also* accentuation. 3. A scheme sometimes adopted during recording to nullify the effect of tracing distortion on replay. The distortion deliberately introduced is the reciprocal of that produced on replay.

Preemphasis/postemphasis curves.

preemphasis network — A network inserted into a system to emphasize one range of frequencies.

preempted process — A process that, because of scheduling policy, must relinquish the processor to another process.

preemptor — A feature of some automated networks by which a high-precedence message, call, or transmission preempts a line from a use of lower precedence if all other lines are busy.

preequalization — *See* preemphasis.

preferred tube types — Tube types recommended to designers of electronic equipment to minimize the number of tube types that must be stocked by the manufacturer or by service agencies.

preferred values — A series of resistor and capacitor values adopted by the EIA and military. In this system, the increase between any two steps is the same percentage as between all other steps. Increases may be in steps of 20 percent, 10 percent, or 5 percent each.

prefired — Conductors fired in advance of the screening of resistors on a substrate.

prefix multipliers — Prefixes that designate a greater or smaller unit than the original, by the factor indicated. These prefixes are as follows:

Prefix	Symbol	Factor
yotta-	Y	10 ²⁴
zeta-	Z	10 ²¹
exa-	E	10 ¹⁸
peta-	P	10 ¹⁵
tera-	T	10 ¹²
giga-	G	10 ⁹
mega-	M	10 ⁶
kilo-	k	10 ³
hecto-	h	10 ²
deka-	da	10
deci-	d	10 ⁻¹
centi-	c	10 ⁻²
milli-	m	10 ⁻³
micro-	μ	10 ⁻⁶
nano-	n	10 ⁻⁹
pico-	p	10 ⁻¹²
femto-	f	10 ⁻¹⁵
atto-	a	10 ⁻¹⁸
zepto-	z	10 ⁻²¹
yocto-	y	10 ⁻²⁴

preform — Also called a biscuit. 1. In disc recording, the small slab of record material used in the presses. 2. Small circle or square of the solder or epoxy punched out of thin sheets. Preforms are placed on the spot to be soldered or bonded, prior to the placing of the object to be attached, to aid in soldering or adhesion.

prelasing condition (or state) — The condition of an injection laser corresponding to the emission of predominantly incoherent or spontaneous radiation.

preliminary contacts — In a relay, contacts that open or close before other contacts when the relay is actuated.

premium service — Extra television programming service for which a subscriber must pay an additional fee above and beyond the basic subscription fee.

preohmic alignment — In a semiconductor, the positioning of the oxide opening into which the metallization is placed.

preohmic window — The opening etched through the oxide in a semiconductor for metallization contact to the emitter and base regions.

preprocessor — 1. A device for placing source records into a format that facilitates system processing in a computer. 2. A method of converting data into computer-usable form for processing and output. 3. Software program or procedure that interprets graphical data and formats it into data readable by a numerical-control machine or by other computer programs.

pre-recorded tape — *See* recorded tape.

prescaler — A circuit that generates an output signal related to the input signal by a fractional scale factor such as 1/2, 1/8, 1/10, etc. An example of a digital prescaler is a decade frequency divider, which has an output frequency one-tenth of the input frequency.

preseal visual — The process of visual inspection (of a completed hybrid circuit assembly) for defects prior to sealing the package.

preselection — 1. The use of a preselector. 2. In buffered computers, a time-saving technique in which a block of information is read into the computer memory ahead of time from whichever input tape will next be called on. 3. In digital computers, a technique whereby data from the next input tape is stored while the computer is still processing other data.

preselector — 1. A device placed ahead of a frequency converter or other device to pass signals of desired frequencies but reduce all others. 2. In automatic

switching, a device that makes its selection before seizing an idle trunk.

preselector stage—A radio-frequency amplifier stage in the input of a superheterodyne receiver.

presence—The quality of naturalness in sound reproduction. When the presence of a system is good, the illusion is that the sounds are being produced intimately at the speaker.

presence control—A potentiometer used in a three-way speaker system for controlling the volume of the middle-range speaker.

presentation—The form that the radar echo signals take on the screen, depending on the nature of the sweep circuit.

presenting—Displaying data in a form that human intelligence can comprehend and use.

preset—1. To establish an initial condition, for example the control values of a loop. 2. An asynchronous input of a flip-flop by which the Q output is set to a logical 1 and the \bar{Q} output is set to a logical 0.

preset guidance system—A guidance system in which the flight path is determined before the missile is launched and cannot be altered after launch.

preset parameter—In a computer, a parameter that is fixed for each problem at a value established by the programmer.

preshoot—The initial transient response to a unidirectional change in input that precedes the main transmission and may be of the same or opposite polarity.

press-button switch—British term for push-button switch.

pressed alumina—Aluminum-oxide ceramic formed by applying pressure to the ceramic powder and a binder prior to firing in a kiln.

pressed stem—An obsolete method of vacuum-tube construction in which all support wires are formed into a flattened piece of glass tubing (actually a relic from the lampmaker's era). *See also* button stem.

press-fit contact—An electrical contact that can be pressed into a hole in an insulator, printed board (with or without plated-through holes), or a metal plate.

press-fit pin—A connector pin that is forced into a wiring board or substrate hole, forming a gas-tight connection point without solder or welds.

pressing—A disc recording produced in a record-molding press from a master or stamper.

press-to-talk switch—Also called a push-to-talk switch. A spring-loaded switch that must be held down as long as the operator talks. Releasing the switch deactivates the microphone. It is used on transmitter and dictating-machine microphones.

pressure—Force per unit area. Measured in pounds per square inch (psi) or by the height (in feet, inches, or centimeters) of a column of water or mercury that the force will support. Absolute pressure is measured with respect to zero pressure. Gage pressure is measured with respect to atmospheric pressure.

pressure alarm system—An alarm system that protects a vault or other enclosed space by maintaining and monitoring a predetermined air-pressure differential between the inside and outside of the space. Equalization of pressure resulting from opening the vault or cutting through the enclosure will be sensed and will initiate an alarm signal.

pressure amplifier—A fluidic device that causes a change in output pressure following a change of sufficient magnitude in control pressure.

pressure amplitude—For a sinusoidal sound wave, the maximum absolute value of the instantaneous sound pressure at a point during any given cycle. The unit is the dyne per square centimeter.

pressure connector—A conductor terminal applied under pressure to make the connection mechanically and electrically more secure. *See also* solderless connector.

pressure-gradient hydrophone—A type of hydrophone in which the electric output is essentially determined by a component of the gradient (space derivative) of the sound pressure.

pressure-gradient microphone—A microphone that reproduces only the difference in acoustic pressure between the front and back of its element. Such microphones are designed to create various pickup patterns through specific acoustic ducting in the microphone case.

pressure hydrophone—A type of hydrophone in which the electric output is essentially determined by the instantaneous sound pressure of the impressed sound wave.

pressure microphone—A microphone in which the electric output corresponds substantially to the instantaneous sound pressure of the impressed sound waves. It is a gradient microphone of zero order, and is nondirectional when its dimensions are smaller than a wavelength.

pressure pad—1. In single-motor tape recorders, a device that forces the tape into intimate contact with the head gap, usually by direct pressure at the head assembly. Felt or similar material, occasionally protected with self-lubricating plastic, is used to apply pressure uniformly and with a minimum of drag to the backing side of the tape. 2. A small piece of cloth or felt that holds the recording tape against the tape heads.

pressure potentiometer—A pressure transducer in which the electrical output is derived by moving a contact arm along a resistance element.

pressure roller—Also called pinch roller, puck, or capstan idler. A spring-loaded rubber-tired roller that holds the magnetic tape tightly against the capstan, permitting the latter to draw the tape off the stock reel and past the heads at a constant speed.

pressure-sensing element—In a pressure transducer, the part that converts the measured pressure into mechanical motion.

pressure spectrum level—The effective sound-pressure level for the sound energy contained within a band 1 hertz wide and centered at a specified frequency. Ordinarily this level is not significant except for sound having a continuous distribution of energy within the frequency range under consideration.

pressure switch—A switch actuated by a change in the pressure of a gas or liquid.

pressure transducer—An instrument that converts a static or dynamic pressure input into the proportionate electrical output.

pressure-type capacitor—A fixed or variable capacitor used chiefly in transmitters. It is mounted inside a metal tank filled with nitrogen at a pressure that may be as great as 300 pounds per square inch (21 kg/cm²). The high pressure permits a voltage rating several times that of air.

pressure unit—A moving-coil speaker drive unit that usually has as its diaphragm a small dome of plastic or metal. It is designed for use in the throat of a horn.

pressurization—The process by which the critical parts of equipment designed for high-altitude operation are surrounded with dry air or an inert gas under pressure (about 5 pounds per square inch, or 0.35 kg/cm², at sea level). Thus, breakdowns from the impaired insulating properties of air at reduced pressure are prevented.

prestore—To store a quantity in an available or convenient location in a computer before it is required in a routine.

pretinned—Refers to solder applied to an electrical component or printed circuit board prior to soldering.

pre-tr—In a radar set, an additional tr box that provides additional attenuation of transmitted pulse to prevent damage to the crystal mixer.

pretravel—The distance or angle through which the actuator moves from the actuator free position to the actuator operating position.

pretrigger—1. A timed pulse used to start a sequence of operations prior to the main trigger. 2. In random-sampling oscilloscope technique, a trigger that occurs or arrives prior to a related signal event. 3. The amount of information that will be stored in a digital oscilloscope memory preceding the trigger event. Typically, up to one sweep interval of pretrigger information can be placed in memory.

pre-tr tube—A gas-filled radio-frequency switching tube used to protect the tr tube from excessive power and the receiver from frequencies other than the fundamental.

preventive maintenance—Precautionary measures taken on a system to forestall failures rather than to eliminate them after they have occurred.

preview—Also called page preview. In word processing, displaying a formatted document on the screen to see exactly what the printed page will look like.

previous-element coding—A method of signal coding for digital television transmission in which each transmitted picture element depends on the similarity of the preceding element.

prewound core—A motor core (stator laminations) that can be removed and replaced by a factory-wound (prewound) stator core.

PRF—Abbreviation for pulse-repetition frequency.

pri—Abbreviation for primary.

primaries—See primary colors.

primary—Abbreviated pri and symbolized by P. Also called a primary winding. 1. A transformer winding that carries current and normally sets up a current in one or more secondary windings. 2. Pertaining to the high-voltage conductors of a power-distribution system. 3. Any one of three lights in terms of which a color is specified by giving the amounts required to duplicate it by additive combination. 4. A transformer winding that receives energy from a supply source and uses it to create a magnetic flux in the transformer core.

primary area—See primary service area.

primary battery—A battery consisting of primary cells.

primary breakdown—Also called avalanche breakdown. The sustaining mode of a transistor—unlike second breakdown, not a failure mode. The transistor collector-to-emitter voltage is relatively constant for different collector supply voltages.

primary calibration—Calibration in which the transducer output is observed or recorded while direct stimulus is applied under controlled conditions.

primary-carrier flow—Also called primary flow. The current flow responsible for the major properties of a semiconductor device.

primary cell—A cell that converts chemical energy into electrical energy by irreversible chemical reactions. It cannot be recharged (like a secondary cell) by passing an electric current through it.

primary circuit—The first, in electrical order, of two or more coupled circuits, wherein a change in current will induce a voltage in the other, or secondary, circuit.

primary colors—Also called primaries. 1. A set of colors from which all other colors are derived; hence, any set of stimuli from which all colors may be produced by mixture. 2. The three colors used in color TV, no two of which can be combined to produce the third: red, green, and blue.

primary current—The current flowing through the primary winding of a transformer. Changes in this current cause a voltage to be induced in the secondary winding of the transformer.

primary detector—Also called a sensing, primary, or initial element. The first system element or group of elements that responds quantitatively to the measurand and performs the initial measurement operation. A primary detector performs the initial conversion or control of measurement energy. It does not include those transformers, amplifiers, shunts, resistors, etc., used as auxiliary means.

primary distribution voltage—Voltage at the primary (high) side of a transformer at a distribution substation.

primary electron—1. After a collision between two electrons, the one with the greater energy. The other is called the secondary electron. 2. The electron produced in a detector or counter tube after ionization.

primary element—See primary detector.

primary emission—Emission of electrons due to primary causes (e.g., heating of a cathode) rather than secondary effects (e.g., electron bombardment).

primary failure—A failure occurring under normal environmental conditions and having no significant relationship to a previous failure but whose occurrence imposes abnormal stress on some other part or parts, which may then undergo a secondary failure.

primary fault—In an electric circuit, initial breakdown of the insulation of a conductor, usually followed by a flow of power current.

primary flow—See primary-carrier flow.

primary frequency—The frequency assigned for normal use on a particular circuit or communications channel.

primary grid emission—See thermionic grid emission.

primary instrument concept—A theory in which single (telephone) line households and businesses would have at least one company-provided telephone; additional ones could be bought elsewhere.

primary insulation—The layer of material that is designed to do the electrical insulating, usually the first layer of material applied over the conductor.

primary ionizing event—See initial ionizing event.

primary power cable—Power service cables connecting the outside power source to the main-office switch and metering equipment.

primary radar—See radar.

primary radiation—Radiation direct from the source without interaction.

primary radiator—The antenna element from which the radiated energy leaves the transmission system.

primary relay—A relay that produces the initial action in a sequence of operations.

primary service area—Also called the primary area. The area within which radio or TV reception is not normally subject to objectionable interference or fading.

primary skip zone—The area beyond the ground-wave range around a transmitter, but within the skip distance. Radio reception is possible in this zone by sporadic and zigzag reflections.

primary standard—1. A unit directly defined and established by some authority, and against which all secondary standards are calibrated. 2. A standard of voltage, current, frequency, etc., precisely defined by the National Bureau of Standards. Portable secondary standards are calibrated against this primary standard.

primary station—The principal amateur radio station at a specific land location shown on the station license.

primary storage—In a computer, the main internal storage.

primary voltage—1. The voltage applied to the terminals of the primary winding in a transformer. 2. The voltage produced by a primary cell.

primary winding—See primary, 1 and 4.

priming illumination—A small, steady illumination applied to a phototube or photoelectric cell to make it more sensitive to variations in the illumination being measured.

primitive period—The smallest increment of time during which a quantity repeats itself.

principal axis—A reference direction for angular coordinates, used in describing the directional characteristics of a transducer employed for sound emission or reception. It is usually an axis of structural symmetry or the direction of maximum response. If these two do not coincide, however, the reference direction must be described explicitly.

principal current—The current through the main terminals of a bidirectional thyristor or through the anode and cathode terminals of a reverse-blocking or a reverse-conducting thyristor.

principal E-plane—The plane containing the direction of maximum radiation and in which the electric vector lies.

principal focus—For a lens or spherical mirror, the point of convergence of light coming from a source at an infinite distance.

principal H-plane—A plane containing the direction of maximum radiation; the electric vector is everywhere normal to the plane, and the magnetic vector lies in it.

principal mode—See dominant mode.

principal voltage—The voltage between the main terminals of a bidirectional thyristor or between the anode and cathode terminals of a reverse-blocking or a reverse-conducting thyristor.

print—The possible output formats of a teletypewriter or electric typewriter terminal. Print refers to tabulated output data; plot refers to a graphical arrangement of the output data performed by the typewriter with symbols such as "x" or "*" used to indicate data points—the plot is discontinuous. Print-plot refers to the availability of both formats at the same terminal.

print and fire—The process wherein the ink is printed on a substrate and is subsequently fired.

printed—Reproduced on a surface by some process (e.g., letterpress, lithography, silk screen, etching).

printed board—The general term for completely processed printed circuit or printed wiring configurations. It includes single, double, and multilayer boards, both rigid and flexible.

printed-board assembly—A printed circuit board to which separable components have been attached. Also an assembly of one or more printed circuit boards that may include several components.

printed cable—A cable having a thin film of copper laid onto insulation and deriving its strength from the insulation rather than from the conductor.

printed circuit—Abbreviated pc. 1. A circuit in which the interconnecting wires have been replaced by conductive strips printed, etched, etc., onto an insulating board. It may also include similarly formed components on the baseboard. 2. A substrate on which a predetermined pattern of printed wiring and printed elements has been formed. 3. A board on which a predetermined pattern of printed connections has been formed.

printed-circuit assembly—1. A printed circuit board to which separate components have been attached.

Printed circuit.

2. An assembly of one or more printed circuit boards that may include several components.

printed circuit board—Abbreviated pcb. Also called a card, chassis, or plate. An insulating board (usually Fiberglas® or plastic) onto which a circuit has been printed. See also printed circuit.

printed-circuit chemicals—All the cleaning solutions, resists, etchants, plating solutions, and similar materials that are specifically applied to the manufacturing of printed circuit boards.

printed-circuit motor—A motor that has a flat plastic rotor with photoetched conductors. The brushes bear directly on these conductors, and a separate commutator is not required. The rotor diameter is relatively large, resulting in wide pole faces. A large magnet is needed to create the necessary magnetic field. In addition, the winding is limited by the number of effective turns that can be printed, limiting the voltage that the motor can be designed to meet. The printed-circuit motor has some distinct advantages. Low armature inertia and low winding resistance give this motor the highest acceleration available. Since there is no iron in the rotor, the motor does not cog.

printed-circuit switch—A special rotary switch that can be connected directly to a mating printed circuit board without wires.

printed component—A type of printed circuit intended primarily for electrical and/or magnetic functions other than point-to-point connections or shielding (e.g., printed inductor, resistor, capacitor, transmission line, etc.).

printed contact—The portion of a printed circuit that connects the circuit to a plug-in receptacle and performs the function of a plug pin.

printed element—An element, such as a resistor, capacitor, or transmission line, that is formed on a circuit board by deposition, etching, etc.

printed wiring—1. A pattern of conductors printed (screened) onto the surface of an insulating base to provide interconnection of active and passive devices to make an electronic circuit. 2. A printed circuit, or a portion thereof, intended primarily to provide point-to-point electrical connections. 3. A conductive pattern within or bonded to the surface of a base material intended for point-to-point connection of separate components and not containing printed components. 4. Conductive patterns etched or bonded to the surface of the base material to establish point-to-point connection of components.

printed wiring substrate—A conductive pattern printed on a substrate.

printer—Also called a teleprinter and teletypewriter. 1. A telegraph instrument with a signal-actuated mechanism for automatically typing received messages. It may have a keyboard similar to that of a typewriter for sending messages. The term *receiving-only* is applied to a printer with no keyboard. 2. A device that prints the output from

a computer. Generally categorized as impact or nonimpact types and serial printers or line printers. 3. A device to provide hard-copy output. Unlike a terminal, there is virtually no communication from printer to central processor. Printers usually output copy more rapidly than hard-copy terminals. 4. An output device that converts electronic signals from the computer into human-readable form, or hard copy. The two major printer types are impact printers and nonimpact printers.

printer telegraph code—A five- or seven-unit code used for operation of a teleprinter, teletypewriter, or similar telegraph printer.

printing—The reproduction of a pattern on a surface by any of various processes, such as vapor deposition, photo etching, embossing, or diffusion.

printing demand meter—An integrated demand meter that prints on a paper tape the demand for each interval and indicates the time it occurred.

printing recorder—An electromechanical device used at a monitoring station that accepts coded signals from alarm lines and converts them to an alphanumeric printed record of the signal received.

printing telegraphy—Telegraph operation in which the received signals are automatically recorded as printed characters.

printout—1. The output of a computer program as recorded by a line printer. 2. *See* display. 3. Computer output printed on paper.

print-plot—*See* print.

print server—A printing processor that provides an interface between compatible peripheral devices on a local area network.

print-through—1. The transfer of the magnetic field from one layer to the next when recorded tape is stored on a reel. (It tends to be more of a problem with thin tapes [less than 1 mil, or 25 μm] and at very high recording levels.) Print-through causes faint “echoes” preceding and following loudly recorded passages, and is aggravated by recording at excessively high levels or by exposing recorded tapes to alternating magnetic fields, as from nearby power transformers.

print wheel—In a wheel printer, the single element providing the character set at one printing position.

priority—1. A property that designates a process' relative urgency. 2. The order in which a system satisfies simultaneous service requests. 3. In a computer program, the number assigned to an event or device that determines the order in which it will receive service. By convention, 0 is the highest priority (usually assigned to power-failure detection). 4. The sequence in which various entries and tasks are processed or peripheral devices are serviced. Priorities are based on analyses of codes associated with an entry or task, or the positional assignment of a peripheral device within a group of devices. Order of importance.

priority indicator—A character group that indicates the relative urgency, and, thus, the order of transmission, of a message.

priority interrupt—*See* interrupt.

priority paging—Pager address that has been designated as a “priority address.” This designation overrides the unit's silent mode of operation.

privacy system—In radio transmission, a system designed to make unauthorized reception difficult.

private-aircraft station—A mobile radio station on board an aircraft not operated as an air carrier.

private automatic branch exchange—*See* PABX.

private automatic exchange—*See* PAX.

private branch exchange—*See* PBX.

private exchange—A telephone exchange that serves a single organization and has no means of connection to a public telephone system.

private line—1. A telephone line that does not go through the central office and is reserved for exclusive use of a single customer. 2. Line of communications dedicated to one customer who leases it for exclusive use. Businesses often have such lines to their offices around the country. 3. *See* dedicated line. 4. A telephone line that serves only one party. An individual line. 5. A communication line that is used only for communication between two points and does not connect with a public telephone system.

private radio carrier—A radio carrier owned and controlled by the central station organization.

privileged instruction—A computer instruction that is available only to the operating system or supervisory programs, and not to the general user.

probability—Mathematically, a number between 0 and 1 that estimates the fraction of experiments (if the same experiment were being repeated many times) in which a particular result would occur. This number can either be a subjective guess or it can be based on the empirical results of some experimentation. It can also be derived for a process so as to give the probable outcome of experimentation.

probability distribution—1. A mathematical model showing a representation of the probabilities for all possible values of a given random variable. 2. A table of numbers or a mathematical expression that indicates the frequency with which each of all possible results of an experiment should occur.

probability of success—The likelihood that an article will function satisfactorily for a stated period of time when subjected to a specified environment.

probability theory—The study of the likelihood of occurrence of chance events. Used to predict behavior of a group, not of a single item in the group.

probable error—The amount of error that, according to the laws of probability, is most likely to occur during a measurement.

probe—1. A resonant conductor that can be placed into a waveguide or cavity resonator to insert or withdraw electromagnetic energy. 2. A test lead that contains an active or passive network and is used with certain types of test equipment. 3. A rod placed into the slotted section of a transmission line to measure the standing-wave ratio or to inject or extract a signal. 4. The method of making a temporary electrical connection to a die so that its electrical properties can be determined. 5. An electrical device used for making contact with a circuit test point for test or debug purposes. 6. The driven element in a microwave dish antenna system. It is located in the feed and converts rf energy in the waveguide to a signal on a transmission line. 7. A pointed conductor used in making electrical contact to a circuit board pad for testing.

Probe, 2 (high-voltage).

probing—1. The determination of radio interference by obtaining the relative interference level in the immediate area of a source by the use of a small insensitive antenna in conjunction with a receiving device. 2. Electrical testing of a semiconductor chip before it is

broken out of the wafer. Electrical contact is made to the chip bonding pads so that defective circuits can be marked to eliminate them from further processing. Only low-current dc tests can be carried out by probing. 3. A testing technique that uses finely tipped probes to make electrical connections to a sample chip.

problem check—A test or tests used to aid in obtaining the correct machine solution to a problem.

problem description—In information processing, a statement of a problem. The statement may include a description of the method of solution.

problem language—The language a computer programmer uses in stating the definition of a problem.

problem-oriented language—In a computer, a source language suited to the description of a specific class of problems.

problem-solving language—A language that can be used to specify a complete solution to a problem.

procedure—Also called an algorithm. 1. In a computer, the course of action taken in solving a problem. 2. A precise step-by-step method for effecting a solution to a problem.

procedure-oriented language—1. A programming language in which the operations to be performed are all executable and their sequence is specified by the user. This term applies to most familiar programming languages. 2. A programming language designed for the convenient expression of procedures used in the solution of a wide class of problems, e.g., FORTRAN, COBOL, APL, and C.

process—1. Any operation or sequence of operations involving a change of energy state, composition, dimension, or other property that may be defined with respect to a datum. The term *process* is used in this standard to apply to all variables other than instrument signals. 2. The basic unit of computation within an operating system. Also termed a software process to distinguish it from an abstract process, which is the task the software process implements.

process control—1. Automatic control of continuous operations, contrasted with numerical control, which provides automatic control of discrete operations. 2. The regulation or manipulation of variables influencing the conduct of a process in such a way as to obtain a product of desired quality and quantity in an efficient manner.

processing—Additional handling, manipulation, consolidation, compositing, etc., of information to change it from one format to another or to convert it to a manageable and/or intelligible form.

processing section—The portion of a computer that does the actual changing of input into output. This includes the arithmetic and logic sections.

processor—1. In hardware, a data processor. 2. In software, a computer program that includes the compiling, assembling, translating, and related functions for a particular programming language, including logic, memory, arithmetic, and control. 3. A unit in the programmable controller that scans all the inputs and outputs in a predetermined order. The processor monitors the status of the inputs and outputs in response to the user-programmed instructions in memory, and it energizes or deenergizes outputs as a result of the logical comparisons made through these instructions. 4. A computer or part of a computer capable of receiving data, manipulating it, and supplying results.

processor status word—Abbreviated PSW. A special-purpose CPU register that contains the status of the most recent instruction execution result, trap bit, and interrupt priority.

producer's reliability risk—The risk faced by the producer (usually set at 10 percent) that a product will be rejected by a reliability-acceptance test even though the product is actually equal to or better than a specified value of reliability.

product detector—A demodulator whose output is the product of the input signal voltage and the signal voltage of a local oscillator operating at the input frequency.

production lot—A group of (electronic) parts manufactured during the same period from the same basic raw materials, processed under the same specifications and procedures, produced with the same equipment, and identified by the documentation defined in the manufacturer's reliability assurance program through all significant manufacturing operations, including final assembly operations. Final assembly operation is considered the last major assembly operation, such as casing, hermetic sealing, or lead attachment, rather than painting or marking.

production sampling tests—Those tests normally made by either the vendor or the purchaser on a portion of a production lot for the purpose of determining the general performance level.

production tests—Those tests normally made on 100 percent of the items in a production lot by the vendor and normally on a sampling basis by the purchaser.

product modulator—A modulator whose output is substantially equal to the carrier times the modulating wave.

professional channel—Subcarrier channel in FM broadcasting. Professional channels are usually 6.5 times the frequency of the pilot carrier, or they may be interspersed between the stereo position and 102 kHz, if there is no SAP (second audio program) conflict.

professional engineer—An engineer whose education and experience qualify him or her to be responsible for important engineering work, and who is registered as a professional engineer by a state authority.

profile chart—A vertical cross-sectional drawing of the microwave path between two stations. Terrain, obstructions, antenna-height requirements, etc., are indicated on the drawing.

program—1. A sequence of instructions that tells a computer how to receive, store, process, and deliver information. 2. A plan for solving a problem, including instructions that cause the computer to perform the desired operations and such necessary information as data description and tables. 3. A prepared list of instructions,

Process-control system.

process-control block—The data structure that defines a software process and its status.

written in a special language or code, to be carried out in sequence by a computer or other programmable device. 4. To design, write, and test such a set of coded instructions. 5. A series of actions proposed in order to achieve a certain result. 6. In a calculator, a sequence of detailed instructions for the operations necessary to solve a problem. Programmable electronic calculators can "learn" the steps of a problem so that, after the first sequence of entries, only the variable numbers need be entered on the keyboard without manual activation of control keys. 7. The statement of an algorithm in some well-defined language. Thus, a computer program represents an algorithm, although the algorithm itself is a mental concept that exists independently of any representation. 8. A set of coded instructions that direct a computer to perform some specific function, yield the solution to some specific problem, or control a machine or process. 9. A sequence of instructions that will execute a predetermined sequence of operations. 10. An organized set of instructions used to control operations of an electronic switching system. 11. A sequence of user-specified instructions that result in the execution of an algorithm. Programs are essentially written at three levels: (a) binary (can be directly executed by the MPU), (b) assembly language (symbolic representation of the binary), and (c) high-level language (such as BASIC; requires a compiler or interpreter). 12. A meaningful assembly of encoded instructions and data formats and data values internal to the program. 13. A sequence of audio signals alone, or audio and video signals, transmitted for entertainment or information.

program amplifier — See line amplifier.

program assembly — Also called translation. A process that translates a symbolic program into a machine-language program before the working program is executed. Several sections or different programs can also be integrated during this process. See also assembler.

program break — The length of a program; the first location not used by a program (before relocation); the relocation constant for the following program (after relocation).

program circuit — A telephone circuit that has been equalized to handle a wider range of frequencies than ordinary speech signals require. In this way, music can be transmitted over telephone wires.

program control — A control system that automatically holds or changes its target value on the basis of time, to follow a prescribed program for the process.

program counter — A CPU register that specifies the address of the next instruction to be fetched and executed. Normally it is incremented automatically each time an instruction is fetched. See also program register.

program-distribution amplifiers — A group of amplifiers fed by a bridging bus from a single source. Each amplifier then feeds a separate line or other service.

program element — The part of a central computer system that performs the sequence of instructions scheduled by the programmer.

program failure alarm — In broadcasting stations, a relay circuit that gives a visual and aural alarm when a program fails. A delay prevents the relay from giving a false alarm during the silence before and after station identification or other short breaks.

program flowchart — A flowchart that describes the control flow—the order in which the various program steps are executed—within any computer program or module.

program generator — A program that enables a computer to write other programs automatically.

Program-distribution amplifiers.

program instruction — A group of letters, symbols, or numbers that direct a computer to perform an operation. (The instruction may also include one or more addresses.)

program level — The measure of the program signal in an audio system. It is expressed in volume units (VU).

program library — A collection of available computer programs and routines.

program linkage — In a computer, efficient use of all registers and development of subroutines so that there is smooth, economical transition from one program segment to another, and memory capacity is conserved.

program loop — A series of computer instructions that are repeated until a terminal condition is achieved.

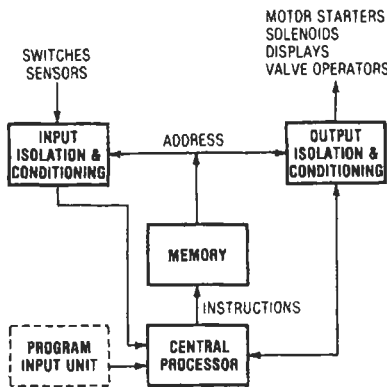

programmable — That characteristic of a device that makes it capable of accepting data to alter the state of its internal circuitry to perform a specific task(s).

programmable calculator — 1. A calculator whose operation is controlled by programs stored in its memory. 2. Electronic calculator capable of performing preset sequences of computations. 3. One that can learn a repetitive series of operations; that is, can be programmed by various means to handle a series of steps so that only variable information need be entered into the calculator.

programmable communications processor — A digital computer that has been specifically programmed to perform one or more control and/or processing functions in a data communications network. As a self-contained system, it may or may not include communications line multiplexers, line adapters, a computer system interface, and online peripherals. It always includes a specific set of user-modifiable software for the communications function.

programmable controller — Abbreviated PC. 1. A control machine based on solid-state digital logic and built of computer subsystems, and primarily intended to take the place of electromechanical relay panels in applications in which rewiring would be made necessary by periodic changes in sequence. This type of controller is particularly useful in the control of processes, materials handling, and certain machine functions. 2. A controller whose operation is determined by codes or instructions programmed into it by the user. 3. A solid-state control system that has a user-programmable memory for storage of instructions to implement specific functions, such as I/O control logic, timing, counting, arithmetic, and data manipulation.

A PC consists of central processor, input/output interface, memory, and programming device, which typically uses relay-equivalent symbols. It is purposely designed as an industrial control system that can perform functions equivalent to a relay panel or a wired solid-state logic control system. 4. A device that provides control of a machine or process on the basis of input conditions received from the machine or process, or other inputs. It is comprised of a central processing unit, memory, and input/output. The central processor accepts inputs, and on the basis of these inputs and the instructions programmed into the unit, determines the appropriate output. The memory portion of the PC stores the instructions. 5. A digitally operating electronic apparatus that uses a programmable memory for the internal storage of instructions for implementing specific functions, such as logic, sequencing, timing, counting, and arithmetic to control, through digital or analog input/output modules, various types of machines or processes. A digital computer that is used to perform the functions of a programmable controller is considered to be within this scope. Excluded are drum and similar mechanical-type sequencing controllers. 6. A device or transmission control unit in which hardware functions have been replaced with software or microcode, so that capabilities can be added, changed, or tailored to the user's needs.

Programmable controller, 1.

programmable counter—Also called modulo-*n* counter. A device capable of being programmed so that it counts to any number from zero to its maximum possible modulus.

programmable logic array—Abbreviated PLA. 1. A general-purpose logic structure consisting of an array of logic circuits. The way in which these circuits are programmed determines how input signals to the PLA are processed. Programming is done on a custom basis at the factory and permanently establishes the functional operation of the PLA. 2. An LSI chip that can implement a combinatorial logic circuit involving usually over ten inputs and eight outputs. The logic is determined by the internal masking of an AND matrix and an OR matrix. 3. An array of logic gates (ANDs, ORs, NANDs, NORs, etc.) all formed on a single IC chip. The gates can be joined together to form any combinatorial logic function desired. Given a certain digital input, the collection of gates will deliver a particular digital output. 4. An arrangement of two device arrays, each with a different type of gate. The PLA's logic functions are determined by the interconnections made between the two

component arrays. PLAs are not space efficient and are more expensive than dedicated circuits, but are easier to design and can be programmed by the system integrator.

programmable logic level—Digital data with high and low levels capable of being varied under computer control.

programmable operational amplifier—An operational amplifier in which some of the parameters (such as input bias current, slew rate, power consumption, noise, etc.) can be set by means of an external resistor.

programmable read-only memory—Abbreviated PROM. 1. An integrated circuit memory array that is manufactured with a pattern of either all logical 0s or 1s and has a specific pattern written into it by the user by a special hardware programmer. (Some PROMs, called EAROMs, can be erased and reprogrammed.) 2. A field-programmable read-only memory that can have the data content of each memory cell altered only once. PROMs are generally bipolar devices programmed by blowing a fusible link.

programmable robot—A servorobot directed by a programmable controller that memorizes a sequence of arm and gripper movements; this routine can then be repeated perpetually. The robot is reprogrammed by leading its gripper through the new task.

programmable unijunction transistor—Abbreviated PUT. A four-layer device similar to a silicon-controlled rectifier except that the anode gate rather than the cathode gate is brought out. It is used in conventional unijunction transistor (UJT) circuits. The characteristics of both devices are similar, but the triggering voltage of the PUT is programmable and can be set by an external resistive voltage divider network. The PUT is faster and more sensitive than the UJT. It finds limited application as a phase-control element and is most often used in long-duration timer circuits. In general, the PUT is a more versatile and more economical device than the UJT. *See also* PUT.

programmatics—The branch of learning that has to do with the study of programming methods and languages.

programmed check—A means of testing for the correctness of a computer program and machine functioning, either by running a similarly programmed sample problem with a known answer (including mathematical or logical checks) or by building a checking system into the actual program being run.

programmed logic array—Abbreviated PLA. An orderly arrangement of logical AND and logical OR functions. Its application is very much like a glorified ROM. It is primarily a combinatorial logic device.

programmed marginal check—A computer program that provides voltage variation to check a tube or other computer equipment during a preventive-maintenance check.

programmed operators—Computer instructions that make it possible for subroutines to be accessed with a single programmed instruction.

programmed wiring—Method by which conductors are attached to a multicontact termination panel by a programmable machine. Applicable to highly dense wiring and high production quantities. Wire attachment is by automatically wrapping the wire around a solid, square, or rectangular terminal.

programmer—1. A person who prepares the sequences of instructions for a computer or other data-handling system. He or she may or may not convert them into detailed codes. 2. A device for timed switching of several interrelated functions or set of functions. 3. A machine or interface that will allow the programming of PROMs.

programming—1. Definition of a computer problem resulting in a flow diagram. 2. Preparing a list

of instructions for the computer to use in the solution of a problem. 3. Selecting various circuit patterns by interconnecting or "jumping" the appropriate contacts on one side of a connector plug. 4. The control of a power-supply parameter, such as output voltage, by means of a remotely located or internally located control element (usually resistance) or signal (voltage). 5. The process of translating a problem from its physical environment to a language that a computer can understand and obey. 6. The process of planning the procedure for solving a problem. This may involve, among other things, an analysis of the problem, establishing input/output formats, establishing testing and checkout procedures, allocation of storage, preparation of documentation, and supervision of the running of the program on a computer. 7. Selecting a circuit pattern from the variety of circuit options offered by a given device. Programmable devices include pin boards, programming systems, and various switches. In addition, programming is sometimes achieved by interconnecting appropriate contacts on one side of a panel or connector plug.

programming device—A device by which a series of mechanical or electrical operations or events may be preset to be performed automatically in a predetermined sequence and at specified time intervals.

programming module—A set of instructions that is discrete and identifiable and usually is handled as a unit by an assembler, compiler, linkage editor, loading routine, or other routine or subroutine.

programming station—A system configured to perform programming tasks only.

programming system—Any method of programming problems, consisting of a language (other than machine language) and its associated processor(s).

program panel—A device for inserting, monitoring, and editing a program in a programmable calculator.

program parameter—In a subroutine of a computing or other data-handling system, an adjustable parameter that can be given different values on several occasions when the subroutine is used.

program register—Also called program counter or control register. The computer control-unit register into which is stored the program instruction being executed, hence controlling the computer operation during the cycles required to execute that instruction.

program scan—The time required for a programmable calculator processor to execute all instructions in the program once. The program scan repeats continuously. The program monitors inputs and controls outputs through the input and output image tables.

program selector—Control that switches an eight-track recorder from one set of tracks to another.

program-sensitive error—In a computer, an error arising from unforeseen behavior of some circuits, discovered when a comparatively unusual combination of program steps occurs.

program signal—In audio systems and components, the complex electric wave—corresponding to speech, music, and associated sounds—destined for audible reproduction.

program step—An increment, usually one instruction, of a computer program.

program storage—A portion of the internal computer storage reserved for programs, routines, and subroutines, as contrasted with temporary storage. In many systems, protective devices are used so that the contents of the program storage cannot be altered inadvertently.

program stubs—Code sections added to a subprogram to make it executable; stubs are usually substitutes for parts of the missing main program.

program tape—In a computer, a magnetic or punched paper tape that contains the sequence of instructions for solving a problem.

program time—The phase of computer operation during which an instruction is being interpreted so that the required action can be performed.

program timer—1. A loosely used term sometimes referring to a complex multicircuit timing device in which the program is readily changed, such as tape-controlled timers, cam timers, time switches, or to any other type of timer. 2. A multiple-circuit repeat-cycle timer that repeats a preset program continuously as long as power is applied.

progressive scanning—A rectilinear process in which adjacent lines are scanned in succession. In television, the scanning process in which the distance from center to center of successively scanned lines is equal to the nominal line width.

projected peak point—The point on the characteristic of a tunnel diode where the current is equal to the peak-point current, but where the voltage is greater than the valley-point voltage.

projected peak-point voltage—The voltage value at the projected peak point.

project engineer—Engineer in charge of a project; may be the designer of the system, and even in charge of purchasing for project.

projection cathode-ray tube—A cathode-ray tube that produces an intense but relatively small image, which can be projected onto a large viewing screen by an optical system consisting of lenses or a combination of lenses and mirrors.

projection PPI—A unit in which the image of a 4-inch (10.1-cm) dark-trace cathode-ray tube is projected on a 24-inch (61-cm) horizontal plotting surface. The echoes appear as magenta-colored arcs on a white background. *See also* dark-trace tube.

projection television—A combination of lenses and mirrors for projecting an enlarged television picture onto a screen.

projection welding—Resistance welding in which heat is localized through embossed or coined projections on the fastener. During the welding process, the projections coalesce with the part surface to form the weld.

projector—1. A device used in an underwater sound system to radiate sound pulses through the water from the bottom of a ship. 2. A horn designed to direct sound chiefly in one direction from a speaker. 3. A lighting unit that, by means of mirrors and lenses, concentrates the light to a limited solid angle so as to obtain a high value of luminous intensity.

PROM—Abbreviation for programmable read-only memory (programmable ROM). 1. A read-only memory that can be written to only once. Programmed after manufacture by external equipment. Typically, PROMs utilize fusible links that are burned open to set a specific memory location to a specific logic level. After a PROM is programmed, it effectively becomes a ROM. 2. Similar to the conventional ROM (read-only memory). A write-once memory. When an instruction is written via a memory-write cycle into the programmable ROM, certain kinds of fusing take place and the data is written permanently into the memory. 3. A digital storage device that can be written into only once but then can be continually read. 4. An integrated-circuit memory array manufactured with a pattern of either all logical 0s or a specific pattern written into it by the user using a special hardware programmer. Some PROMs, called EAROMs (electrically alterable read-only memory), can be erased and reprogrammed.

promethium cell—A low-power cell containing a radioactive isotope called promethium 147, which emits

beta particles that strike a phosphor. Two photocells then convert the light output from the phosphor into electrical energy.

prompt—1. A symbol that alerts the user that a device is online and connected to a channel for transmission. 2. Information sent to a PC from the remote computer requesting more input. 3. An on-screen hint to the user about what to do next.

prong—*See* pin.

proof pressure—1. The maximum pressure that may be applied to the sensing element of a transducer without changing the transducer performance beyond specified tolerances. 2. The maximum pressure that a diaphragm, capsule, or element can withstand without permanent deformation. Expressed in terms of input pressure.

propagated error—An error that is carried through succeeding computer operations.

propagation—Also called wave propagation. 1. The travel of electromagnetic waves or sound waves through a medium. Propagation does not refer to the flow of current in the ordinary sense. 2. The means by which radio signals are carried from one location to another.

propagation anomaly—An irregularity introduced into an electromagnetic or other sensing device by discontinuities in the propagation medium.

propagation constant—1. The transmission characteristic that indicates the effect of a line on a wave being transmitted along the line. It is a complex quantity having a real term called the attenuation constant and an imaginary term called the phase constant. 2. Also called transfer factor. The natural logarithm of the ratio of the current into an electric transducer to the current out of the transducer, with the transducer terminated in its iterative impedance.

propagation delay—1. A measure of the time required for a logic signal to travel through a device or a series of devices forming a logic string. It occurs as the result of four types of circuit delays—storage, rise, fall, and turn-on delay—and is the time between when the input signal crosses the threshold-voltage point and when the responding voltage at the output crosses the same voltage point. 2. Time delay occurring between the application of an input to a digital logic circuit and the change of state at the output. 3. The time necessary for a signal to travel from one point in a circuit to another. 4. The time required for a pulse or a level transition to propagate through a device. 5. *See* insertion delay.

propagation error—For ranging systems, the algebraic sum of propagation-velocity error and curved-path error. Except at long ranges and low angles, the curved-path component of propagation error is generally negligible.

propagation factor—*See* propagation ratio.

propagation loss—The loss of energy suffered by a signal while passing between two points.

propagation ratio—Also called the propagation factor. For a wave that has been propagated from one point to another, the ratio of the complex electric-field strength at the second point to that at the first point.

propagation time—1. The time it takes for a signal to travel from point to point. In a communications channel, the velocity of signal propagation is less than that of radio. A signal delay of 20 ms per thousand miles or 1600 kilometers is a reasonable maximum. 2. The time required for transmission of a unit of binary information (high or low voltage) from one physical point in a system or subsystem to another, such as from the input to the output of a device.

propagation time delay—The time required for a wave to travel from one point to another along a transmission line. It varies according to the type of line.

propagation velocity—*See* velocity of propagation.

property sort—In a computer, a technique for the selection of records meeting a certain criterion from a file.

proportional—1. A linear (straight line) relationship between two variables. 2. Method of printing characters in which each character takes up only the horizontal space it needs, rather than a fixed amount of space, e.g., the character "i" takes up less space than "m."

proportional band—The range of the controlled variable corresponding to the full range of operation of the final control element.

proportional control—1. A method of control in which the intensity of action varies linearly as the condition being regulated deviates from the conditions prescribed. 2. Also called galloping ghost. An advanced type of radio-control system in which the rudder (and sometimes the elevator) can move as much (or as little) as the operator wishes. 3. A control system in which corrective action is always proportionate to any variation of the controlled process from its desired value. For example, instead of snapping directly open-closed in the manner of two-position control, a proportional valve will be always positioned at some point between open and closed, depending on the flow requirement of the system at any given moment.

proportional counter tube—A sealed tube containing an inert gas such as argon, krypton, xenon, methyl bromide, etc. It is used like a Geiger-Mueller counter and operated at about 100 volts in the proportional region.

proportional linearity—A manner of expressing nonlinearity as the deviation from a straight line in terms of a given percentage of the transducer output at the stimulus point under consideration (i.e., as a percentage of the reading).

proportional region—In a radiation counter tube, the applied-voltage range in which the gas amplification is greater than unity and is independent of the charge liberated by the initial ionizing event.

proportional temperature control—A method of stabilizing (an oscillator) by providing heater power that is directly proportional to the difference between the desired operating temperature and the ambient temperature.

proprietary alarm system—An alarm system that is similar to a central station alarm system except that the annunciator is located in a constantly manned guard room maintained by the owner for his or her own internal security operations. The guards monitor the system and respond to all alarm signals or alert local law enforcement agencies, or both.

protected area—An area monitored by an alarm system or guards, or enclosed by a suitable barrier.

protected location—A computer storage location reserved for special purposes, in which data cannot be stored without being subjected to a screening procedure to establish suitability for storage at that location.

protected memory—Storage (memory) locations reserved for special purposes, in which data cannot be entered directly by the user.

protected port—A point of entry, such as a door, window, or corridor, that is monitored by sensors connected to an alarm system.

protected wireline distribution system—Also known as approved circuit. A communications system to which electromagnetic and physical safeguards have been applied to permit secure electrical transmission of unencrypted, classified information, and that has been approved by the cognizant department or agency. The

associated facilities include all equipment and wirelines so safeguarded. Major components are wirelines, subscriber sets, and terminal equipment.

protection — An operating system service that prevents a task from interfering with the execution of another task.

protection device — 1. A sensor such as a grid, foil, contact, or photoelectric sensor connected into an intrusion alarm system. 2. A barrier that inhibits intrusion, such as a grill, lock, fence, or wall.

protective cable — Small-gage quadded cable used in toll cables to serve as fuses, usually at building entrances.

protective device — Any device for keeping an undesirably large current, voltage, or power out of a given part of an electric circuit.

protective gap — A spark gap provided between a conductor and the earth by suitable electrodes. High-voltage surges due to lightning are thus permitted to pass harmlessly to earth through the gap.

protective relay — A relay whose principal function is to protect services from interruption or to prevent or limit damage to apparatus.

protective resistance — A resistance placed in series with a device (e.g., a gas tube) to limit the current to a safe value.

protective signaling — The initiation, transmission, and reception of signals involved in the detection and prevention of property loss due to fire, burglary, or other destructive conditions. Also, the electronic supervision of persons and equipment concerned with this detection and prevention. *See also* line supervision; supervisory alarm system.

protector — 1. A device to protect equipment or personnel from high voltage or current. 2. A protective device used on communication systems to limit the magnitude of extraneous overvoltages. The discharge device within a protector may consist of closely spaced carbon electrodes discharging in air, or metallic electrodes discharging in a hermetically sealed gaseous atmosphere at reduced pressure. A protector does not contain an element to prevent holdover, as in the case of an arrester.

protector block — A rectangular piece of carbon with an insulated metal insert, or porcelain with a carbon insert, that makes one element of a protector. It forms the gap that will break down and provide a path to ground for voltages over 350 volts.

protector tube — A glow-discharge cold-cathode tube in which a low-voltage breakdown is employed between two or more electrodes to protect the circuit against overvoltage.

protocol — 1. A set of conventions or rules governing the format and timing of message exchanges to control data movements and correct errors. It is important to ensure that the protocol is valid, makes sense, works, and is adhered to by all users of the network in question. 2. The set of multiprocessor system rules that define response sequences (handshaking) and maintain the servicing priorities of the system. 3. A defined means of establishing criteria for receiving and transmitting data through communication channels. 4. A formal set of conventions governing the format and control of inputs and outputs between two communicating processes, including handshaking and line discipline. 5. A set of conventions for the transfer of information between devices. The simplest protocols define only the hardware configuration. More complex protocols define timings, data formats, error detection and correction techniques, and software structures. The most powerful protocols describe each level of the transfer process as a layer separate from the rest, so that certain layers such as the interconnecting

hardware can be changed without affecting the whole. 6. The convention by which data is transmitted over a line. Most word processors employ either an asynchronous or synchronous protocol. With an asynchronous protocol, data is transmitted a character at a time, with a start and stop bit transmitted before and after each character to ensure correct receipt. Synchronous protocol is a form of transmission that uses no redundant information (such as the start and stop bits in asynchronous transmission) to identify the beginning and end of each character.

proton — One of the three basic subatomic particles, with a positive charge equivalent to the negative charge of the electron, but with approximately 1845 times the mass. The proton has a positive electric charge of 1.6×10^{-19} coulomb and a mass of 1 amu. The proton is the positive nucleus of the hydrogen atom.

prototype — 1. Original design or first operating model. 2. A development or first production model of a circuit, device, or system.

prototype model — A working model, usually hand-assembled, that is suitable for complete evaluation of mechanical and electrical form, design, and performance. Approved parts are employed throughout, so that it will be completely representative of the final, mass-produced equipment.

prototyping kit — A hardware system used to bread-board a microprocessor-based product. Contains CPU, memory, basic I/O, power supply, switches and lamps, provisions for custom I/O controllers, memory expansion, and, often, a utility program in fixed memory (ROM).

proximity alarm system — *See* capacitance alarm system.

proximity detector — A sensing device that gives an indication when approaching or being approached by another object.

proximity effect — The redistribution of current brought about in a conductor by the presence of another current-carrying conductor.

proximity fuse — A fuse designed to detonate a projectile, bomb, mine, or charge when activated by an external influence in the vicinity of a target. The variable time fuse is one type of proximity fuse.

proximity switch — A device that reacts to the proximity of an actuating means without physical contact or connection.

PRR — Abbreviation for pulse-repetition rate.

PRV (or PIV) rating — Abbreviation for peak reverse voltage or peak inverse voltage. The maximum instantaneous value of reversing voltage allowable across a diode or similar device.

ps — Letter symbol for picosecond (10^{-12} second).

PSD — Abbreviation for power spectral density. The function of the variance of a random process with frequency, used to describe distribution of signal power in the frequency domain.

pseudocode — 1. An instruction that is not meant to be followed directly by a computer. Instead, it initiates the linking of a subroutine into the main program. 2. A series of natural-language statements arranged in a manner resembling a program. There is no firm connection with any actual programming language. Used for instructional purposes or as a preliminary rough sketch of a program.

pseudodifferential input — Amplifier input configuration in which the reference point is other than ground.

pseudoinstruction — A user-defined instruction (such as a macro) that does not belong to the basic instruction set of an MPU.

pseudo-op — 1. An operation that is not part of the computer's operation repertoire as realized by hardware; hence, an extension of the set of machine operations.

2. A directive used in assembly language to control the operation of the assembler. The pseudo-op does not appear in the machine-language program produced by the assembler. A typical pseudo-op is the word "END" written at the end of a program to tell the assembler its work is done.

pseudoprogram—A program that is written in a pseudocode and may include short coded logical routines.

pseudorandom—1. Having the property of being produced by a definite calculation process while simultaneously satisfying one or more of the standard tests for statistical randomness. 2. An apparently random output that has been created by an algorithm.

pseudorandom binary sequence—A two-level signal that has a repetitive sequence, but a random pattern within the sequence. Such a signal finds use as a test signal since it has the basic characteristics of noise, but in terms of parameters that are easily controlled.

pseudorandom number sequence—A sequence of numbers, determined by some defined arithmetic process, that is satisfactorily random for a given purpose, such as by satisfying one or more of the standard statistical tests for randomness. Such a sequence may approximate any one of several statistical distributions, such as the uniform distribution or normal Gaussian distribution.

pseudorandom patterns—1. A sequence of digital patterns, determined by some defined process that is satisfactorily random to perform its intended function. 2. A repeatable sequence of input test patterns that appears statistically random. 3. A repeatable sequence of digital patterns that has the appearance of being random.

pseudoshot noise—*See* partition noise.

pseudostereo—Devices and techniques for obtaining stereo qualities from one channel.

psophometric emf—The electromotive force (or voltage) generated by a source having an internal resistance of 600 ohms and no internal reactance, which, when connected across a standard receiver having 600 ohms of resistance and no reactance, produces the same sinusoidal current as an 800-hertz generator having the same impedance. *See also* psophometric voltage.

psophometric voltage—The voltage that would appear across a 600-ohm resistance connected between any two points in a telephone circuit. (This value is one-half the psophometric emf, since the latter is essentially the open-circuit potential necessary from a source to produce the psophometric voltage if the source has a 600-ohm internal resistance.)

PSOS—A term used by some companies to denote p-channel silicon gate devices.

PSPS—Abbreviation for planar silicon photoswitch.

PSW—Abbreviation for processor status word.

psychoacoustics—A relatively new branch of audio that concerns itself with personal and subjective factors in hearing and in evaluating the performance of high-fidelity equipment.

PTM—Abbreviation for pulse-time modulation.

PTM/PPM/AM—A system in which a number of pulse-position or pulse-time modulated subcarriers are used to amplitude modulate the carrier.

PTT—1. Abbreviation for postal telephone and telegraph. A generic term for European telephone companies, which are generally operated by the country's postal service. 2. Abbreviation for press-to-talk or push-to-talk, generally with reference to a push-button switch on a microphone that is operated to turn the transmitter on and is released to enable the receiver.

p-type—Pertaining to semiconductor material that has been doped with an excess of acceptor impurity atoms so that free holes are produced in the material.

p-type conductivity—The conductivity associated with the holes in a semiconductor.

p-type conductor—A positive-type conductor, one with electron holes as the principal carriers. This implies the presence of acceptors.

p-type crystal rectifier—A crystal rectifier in which forward current flows whenever the semiconductor is more positive than the metal.

p-type material—1. A pure crystal of semiconductor material to which an impurity has been added (electron acceptor such as boron or gallium) to give it a deficiency of electrons and alter its electrical characteristics. 2. Semiconductor material having holes as the majority charge carriers; formed by doping with acceptor atoms. 3. Refers to an excess of positive electrical charges in a semiconductor material. Natural silicon is made to be p-type by the addition of an acceptor impurity.

p-type region—Portion of semiconductor material containing a small number of dopant atoms that have an electron deficiency (an empty space) in their outer orbit. The deficiency is called a hole and behaves like a positively charged particle. The p-type region is a source of mobile positive charges.

p-type semiconductor—1. An extrinsic semiconductor in which the hole density exceeds the conduction-electron density. By implication, the net ionized impurity concentration is an acceptor type. 2. A semiconductor material doped so that it has a net deficiency of free electrons. It therefore conducts electricity through movement of holes. 3. Impurity semiconductor material containing a predominance of acceptor dopants, and in which valence-band holes normally form the principal current carriers.

public-address system—Also called a PA system. One or more microphones, an audio-frequency system, and one or more speakers used for picking up and amplifying sounds to a large audience, either indoors or out.

publication language—A well-defined form of a programming language suitable for printing. A publication language is necessary because some languages use special characters that are not available in normal type.

public communications service—Telephone or telegraph service provided for the transmission of unofficial communications for the public.

public correspondence—Any telecommunication that the offices and stations, by reason of their being at the disposal of the public, must accept for transmission.

public radiocommunication services—Land mobile or fixed radio services, the stations of which are open to public correspondence.

public-safety radio service—Any radio-communication service essential either to the discharge of non-federal governmental functions relating to public-safety responsibilities or to the alleviation of an emergency endangering life or property. The radio transmitting facilities in this service may be fixed, land, or mobile stations.

public switched network—Any switching system that provides circuit switching to many customers. In the United States there are four such networks: Telex, TWX, telephone, and Broadband Exchange.

puck—1. Manually operated directional control device used to input coordinate data. 2. *See* pressure roller.

pucker pocket—A small, angular vacuum column that isolates the magnetic tape and air mass of a vacuum-column drive's main (large) columns from the large accelerations of the tape in the head area.

puff—British abbreviation for picofarad.

pull—1. To cause an oscillator to depart from its designed frequency of operation. 2. To depart from the designed frequency of operation, as an oscillator. 3. Retrieving a byte of data from the data stack.

pull curves—The characteristics relating force to displacement in the actuating system of a relay.

pull-down resistor—1. A resistor connected across the output of a device or circuit to hold the output equal to or less than the zero input level of the following digital device. Also used to lower the output impedance of a device. 2. A resistor connected to a negative voltage or to ground.

pull-in current (or voltage)—The maximum current (or voltage) required to operate a relay. *See also* pickup current.

pulling—1. In an oscillator, the undesired change from the desired frequency. It is caused either by coupling from another source of frequency or by the influence of the load impedance. 2. In television, partial loss of synchronization.

pulling figure—The difference between the maximum and minimum frequencies of an oscillator whenever the phase angle of the load-impedance reflection coefficient varied through 360° . The absolute value of this coefficient is constant and equal to 0.20.

pull-in rate—The maximum stepping rate at which a stepper motor can start its load without missing a step.

pull-in torque—1. Torque that a synchronous motor can exert to bring its driven load into synchronous speed. There is no corresponding term for induction motors. 2. A measure of the maximum torque that can be applied to the shaft of a stepper motor without causing it to miss a step when starting.

pull-out force—The tensile force required to separate a conductor from a contact or terminal, or to separate a contact from a connector.

pull-out rate—The maximum stepping rate at which a stepper motor can move its load without losing synchronism with the field.

pull-out torque—Also called breakdown torque, or maximum torque. 1. The maximum torque a motor can deliver without stalling. 2. *See* running torque. 3. The maximum torque that a synchronous motor develops at synchronous speed at rated frequency and normal excitation. 4. A measure of the maximum torque that can be applied to the shaft of a stepper motor running at a constant speed within its pull-out ratings before the motor loses synchronism with the field.

pull strength—The values of the pressure achieved in a test in which a pulling stress is applied to determine breaking strength of a lead or bond.

pull test—A test for bond strength of a lead, interconnecting wire, or a conductor.

pull the plug—CB radio term for shut off the radio.

pull-up—1. The placing of the output voltage of a logic circuit at the high level by means of an internal current sink or source. 2. A dc voltage imposed on the input of an amplifier to move the amplifier's operating point out of the offset range. Pull-up is usually accomplished by means of a voltage divider network.

pull-up resistor—1. A resistor connected to the positive supply voltage of a transistor circuit, as from the collector supply to the output collector. 2. A resistor connected across the output of a device or circuit to hold the output voltage equal to or greater than the input transition level of a digital device. It is usually connected to a positive voltage or to the plus supply.

pull-up torque—1. The minimum torque developed by an alternating-current motor during the period of acceleration from rest to the speed at which breakdown torque occurs. For motors that do not have a definite breakdown torque, the pull-up torque is the minimum torque developed up to rated speed. 2. Lowest value of torque produced by a motor between zero speed and full-load speed.

pulsating current—Current that varies in amplitude but does not change polarity.

pulsating direct current—A direct current that changes its value at regular or irregular intervals but flows in the same direction at all times.

pulsating electromotive force—A direct electromotive force and an alternating electromotive force combined.

pulsating quantity—A periodic quantity that can be considered the sum of a continuous component and an alternating component in the quantity.

pulsation welding—A form of resistance welding in which the power is alternately applied and removed.

pulse—1. A variation of a quantity whose value is normally constant; this variation is characterized by a rise and a decay and has finite amplitude and duration. 2. An abrupt change in voltage, either positive or negative, that conveys information to a circuit. *See also* impulse. 3. A brief excursion of a quantity from normal. 4. Signal characterized by the rise and decay in time of a quantity whose value is normally constant. 5. Voltage level, typically 5 volts of very short duration, used in computers to represent a bit. 6. Single impulse of a telephone dial. Generally transmitted in groups of one to ten to represent dialed digits or unique tones to represent digits. 7. A sudden and abrupt jump in an electrical quantity from its usual level to a higher or lower value, quickly followed by an equally abrupt return. 8. A voltage or current that lasts for a short period and is square or Gaussian in shape.

Pulse, 1.

pulse amplification—The compression and intensification of a laser pulse of a specific width into a smaller pulse width. A spherical cavity, in conjunction with a beam compressor, is efficient for pulse amplification. Cones and flats are highly effective when used in conjunction with swept-line foci.

pulse amplifier—A wideband amplifier used to amplify square waves without appreciably changing their shape.

pulse amplitude—A general term for the magnitude of a pulse. For more specific designation, adjectives such as average, instantaneous, peak, rms (effective), etc., should also be used.

pulse-amplitude modulation — Abbreviated PAM. Modulation in which the modulating wave is caused to amplitude modulate a pulse carrier.

pulse-amplitude modulation/frequency modulation — A system in which a carrier is frequency modulated by pulse-amplitude-modulated subcarriers.

pulse analyzer — 1. Equipment for analyzing pulses to determine their time, amplitude, duration, shape, etc. 2. The instrument used to analyze a pulsed electromagnetic wave to determine its time, amplitude, duration, and shape, and to display this information in some appropriate form, either visually or digitally.

pulse arc welding — A type of welding in which the material to be welded is positioned together, forming one electrode. The other electrode is positioned to form a gap with one of the workpieces. An arc is struck and the current heats the work-pieces to the melting point at their interface. *See also* arc percussive welding.

pulse average time — The duration of a pulse, measured between two points at 50 percent of the maximum amplitude on the leading and trailing edges.

pulse bandwidth — The smallest continuous frequency interval outside of which the amplitude of the spectrum does not exceed a prescribed fraction of the amplitude at a specified frequency.

pulse capacitor — A capacitor for use with pulses of current or voltage.

pulse carrier — A carrier consisting of a series of pulses. Usually employed as a subcarrier.

pulse code — 1. A pulse or series of pulses that, by means of waveform, pulse width, pulse time, pulse numbers, or pulse sequences, may be used to convey information. 2. Loosely, a code consisting of pulses; e.g., Morse, Baudot, binary.

pulse code modulation — Abbreviated PCM. 1. Pulsed modulation in which the signal is sampled periodically and each sample is quantized and transmitted as a digital binary code. 2. A digital technique by which information may be carried from one point to another. The signal is carried as a series of separate pulses or digits. No distortion is introduced and no information is lost from a signal unless a complete pulse disappears or unless a spurious noise pulse is formed that is large enough to be accepted by the equipment as a genuine pulse. Thus, many channels of communication can be made available along a single connecting line. 3. A method of quantizing audio-range analog signals into a digital form for transmission in digital communications systems, or for processing in DSP. Effectively the same as analog-to-digital conversion. 4. A time-division modulation technique in which analog signals are stamped and quantized at periodic intervals into digital signals. The values observed are typically represented by a coded arrangement of 8 bits, of which one may be for parity.

pulse-code modulation/frequency modulation — A system in which pulse-code-modulated subcarriers are used to frequency modulate a second carrier. Binary digits are formed by the absence or presence of a pulse in an assigned position.

pulse coder — A circuit that sets up pulses in an identifiable pattern.

pulse coding and correlation — A general technique concerning a variety of methods used to change the transmitted waveform and then decode upon its reception. Pulse compression is a special form of pulse coding and correlation.

pulse compression — A matched filter technique used to discriminate against signals that do not correspond to the transmitted signal.

pulse counter — A device that gives an indication or record of the total number of pulses that it has received during a given time interval.

pulse counter detector — A device designed to detect frequency-modulated signals by forming a uni-directional pulse from each sine wave. The direct current of the pulse is proportional to the frequency of the frequency-modulation signal.

pulsed Doppler system — A pulsed radar system that utilizes the Doppler effect to obtain information about the target (not including simple resolution from fixed targets).

pulse decay time — The amount of time required for the trailing edge of a pulse to decay from 90 percent to 10 percent of the peak pulse amplitude.

pulse delay time — The time interval between the leading edges of the input and output pulses, measured at 10 percent of their maximum amplitude.

pulse demoder — Also called a constant delay discriminator. A circuit that responds only to pulse signals with a specified spacing between them.

pulse dialing — Older form of phone dialing, utilizing breaks in dc current to indicate the number being dialed.

pulse digit — A code element comprising the immediately associated train of pulses.

pulse-digit spacing — The time interval between the end of one pulse digit and the start of the next.

pulse discriminator — A device that responds only to pulses having a particular characteristic (e.g., duration, amplitude, period). One that responds to period is also called a time discriminator.

pulse dispersion — In fiber optics, separation or spreading of input optical signals along the length of the optical fiber. Pulse dispersion is expressed in time and distance as nanoseconds and is sometimes called pulse spreading.

pulsed laser — A laser that emits energy in a wave of short bursts or pulses and remains inactive between each burst or pulse. The frequency of the pulses is termed the pulse repetition frequency.

pulsed light — A beam of visible radiant energy of finite duration. The beam rises to a finite amplitude and decays to the same value from which it rose.

pulsed oscillator — 1. An oscillator in which oscillations are sustained by either self-generated or external pulses. 2. An oscillator that generates a carrier-frequency pulse or a train of pulses.

pulsed-oscillator starting time — The interval between the leading-edge times of the pulse at the oscillator control terminals and the related output pulse.

pulsed power supply — A supply that delivers power in pulses, rather than continuously.

pulsed radiance — The integral of the radiance over exposure time.

pulse droop — Distortion characterized by a slanting of the top of an otherwise essentially flat-topped rectangular pulse.

pulsed ruby laser — A laser that uses ruby as the active material. The extremely high pumping power required is obtained by discharging a bank of energy storage capacitors through a special high-intensity flash tube. *See* figure on page 599.

pulse duration — Also called pulse length or pulse width. 1. The time interval between the points at which the instantaneous value on the leading and trailing edges bears a specified relationship to the peak pulse amplitude. 2. The lifetime of a (laser) pulse, generally defined as the time interval between the half-power points on the leading and trailing edges of the pulse.

Pulsed ruby laser.

pulse-duration discriminator — A circuit in which the sense and magnitude of the output is a function of the deviation of the pulse length from a reference.

pulse-duration modulation — Abbreviated PDM. Also called by the less preferred terms pulse-width modulation and pulse-length modulation. 1. Pulse-time modulation in which the duration of a pulse is varied. 2. Pulse-time modulation in which the value of each instantaneous sample of the modulating wave is caused to modulate the duration of a pulse.

pulse-duration modulation/frequency modulation — Also called pulse-width modulation/frequency modulation. A system in which pulse-duration-modulated subcarriers are used to frequency modulate a second carrier.

pulse duty factor — Ratio of the average pulse duration to the average pulse spacing. Equivalent to the average pulse duration times the pulse-repetition rate.

pulse emission — Emission drawn for short periods; it may or may not follow a regular repetition rate.

pulse emitter load — The load seen by the collector of an inverter that drives the pulse input to a flip-flop, pulse amplifier, or delay.

pulse equalizer — A circuit that produces output pulses of uniform size and shape when driven by input pulses that vary in size and shape.

pulse fall time — That time during which the trailing edge of a pulse is decreasing from 90 percent to 10 percent of its maximum amplitude.

pulse-forming line — A combination of circuit components used to produce a square pulse of controlled duration.

pulse-forming network — A network that converts either an ac or dc charging source into an approximately rectangular wave output. By means of a high-speed switch, it alternately stores energy from the charging source and releases the energy through the load to which it is connected. This network supplies the accurately shaped pulse required by the magnetron or klystron oscillator of a radar modulator.

Pulse-forming network.

pulse-duration discriminator — pulse mode

pulse-frequency modulation — Abbreviated PFM. More precisely called pulse-repetition-rate modulation. 1. Pulse-time modulation in which the pulse repetition rate is varied. 2. A form of modulation in which the pulse repetition rate is varied as a function of the instantaneous value of the modulating wave.

pulse-frequency spectrum — See pulse spectrum.

pulse generator — 1. A device for generating a controlled series of electrical pulses. 2. A device that produces a single pulse or a train of repetitive pulses.

pulse group — See pulse train.

pulse-height analyzer — Also called kicksorter. An instrument that indicates the number or rate of occurrence of pulses within each of one or more specified amplitude ranges.

pulse-height discriminator — Also called a pulse-height selector. A circuit that selects and passes only those pulses that exceed a certain minimum amplitude.

pulse-height selector — See pulse-height discriminator.

pulse-improvement threshold — In a constant-amplitude pulse-modulation system, the condition existing when the peak pulse voltage is at least twice the peak noise voltage after selection and before any nonlinear process such as amplitude clipping and limiting. The ratio of peak to rms noise voltage is ordinarily assumed to be 4 to 1.

pulse-interference eliminator — A device that removes pulse signals that are not precisely on the radar operating frequency.

pulse-interference separator and blanker — A circuit that automatically blanks all video signals that are not synchronous with the radar pulse-repetition frequency.

pulse interleaving — A process in which pulses from two or more time-division multiplexers are systematically combined in time division for transmission over a common path.

pulse interrogation — 1. The triggering of a transponder by a pulse or pulse mode. Interrogations by the latter may be employed to trigger one or more transponders. 2. Periodic electrical activation and observation, either synchronous or asynchronous, of the shaft position of an encoder.

pulse interval — See pulse spacing.

pulse-interval jitter — The time or displacement band within which lie all of the transitions in the same direction of a signal through a specified amplitude. This is a dynamic value to be determined at one or more specified speeds. Pulse-interval jitter is expressed as a percentage of one pulse interval at a specified speed.

pulse-interval modulation — Pulse-time modulation in which the pulse spacing is varied. See also pulse-spacing modulation.

pulse jitter — A relatively slight variation of the pulse spacing in a pulse train. It may be random or systematic, depending on its origin, and is generally not coherent with any imposed pulse modulation.

pulse length — See pulse duration.

pulse-length modulation — See pulse-duration modulation.

pulse-link repeater — In a telephone signaling system, equipment that receives pulses from one E and M signaling circuit and transmits corresponding pulses into another E and M signaling circuit.

pulse load — The load presented to a pulse source.

pulse mode — 1. A finite sequence of pulses in a prearranged pattern, used for selecting and isolating a communication channel. 2. The prearranged pattern in (1) above.

pulse-mode multiplex—A process or device for selecting channels by means of pulse modes. In this way, two or more channels can use the same carrier frequency.

pulse moder—A device for producing a pulse mode. *See also* pulse demoder.

pulse-modulated jamming—The use of jamming pulses that have various widths and repetition rates.

pulse-modulated radar—Radar in which the radiation consists of a series of discrete pulses.

pulse-modulated waves—Recurrent wave trains used extensively in radar. In general, their duration is shorter than the interval between them.

pulse modulation—1. The use of a series of pulses modulated to convey information. Modulation may involve changes of pulse amplitude (PAM), position (PPM), or duration (PDM). 2. Modulation of a carrier by a train of pulses: the generation of carrier-frequency pulses. 3. Modulation of a characteristic or characteristics of a pulse carrier: transmission of information on a pulse carrier.

pulse modulator—A device that applies pulses to the element being modulated.

pulse numbers modulation—A type of modulation in which the pulse density per unit time of a carrier is varied in accordance with a modulating wave; omissions of pulses are made systematically without changing the phase or amplitude of the transmitted pulses. For example, the omission of every other pulse could represent zero modulation; the reinsertion of pulses would then represent positive modulation, and the omission of more pulses would represent negative modulation.

pulse operation—The method whereby the energy is delivered in pulses. Usually described in terms of the shape and the frequency of the pulses.

pulse oscillator—An oscillator in which the oscillations are sustained by self-generated or external pulses.

pulse packet—In radar, the volume of space occupied by the pulse energy.

pulse period—Also called impulse period. In telephony, the time required for the dial pulse springs to open and close one time.

pulse-position modulation—Abbreviated PPM. 1. Pulse-time modulation in which the value of each instantaneous sample of the wave modulates the position in time of a pulse. 2. Modulation in which a pulse is delayed from its normal position in time as a function of the modulating wave.

pulse-position modulator—A device that converts analog information to variations in pulse position.

pulsar—A generator that produces extremely short, high-voltage pulses at definite recurrence rates for use in radar transmitters and similar pulsed systems.

pulse rate—1. *See* pulse-repetition rate. 2. The rate at which pulses are fed to a drive of a stepper motor. In most cases, the pulse rate equals the stepping or running rate.

pulse ratio—Ratio of the length of any pulse to its total period.

pulse recovery—The time, usually in microseconds, required for electron flow in a diode to start or stop when voltage is suddenly applied or removed.

pulse-recurrence counting-type frequency meter—A device for measuring frequency. It uses a direct-current ammeter calibrated in pulses per second.

pulse-recurrence time—The time elapsing between the start of one transmitted pulse and the next pulse. The reciprocal of the pulse-recurrence frequency.

pulse regeneration—The restoring of a series of pulses to their original timing, form, and relative magnitude.

pulse repeater—Also called a transponder. A device that receives pulses from one circuit and transmits corresponding pulses at another frequency, waveshape, etc., into another circuit.

pulse-repetition frequency—Abbreviated PRF. The rate (usually given in hertz or pulses per second) at which pulses or pulse groups are transmitted from a radar set.

pulse-repetition period—The reciprocal of the pulse-repetition frequency.

pulse-repetition rate—Abbreviated PRR. Also called pulse rate. The average number of pulses per unit of time.

pulse-repetition-rate modulation—*See* pulse-frequency modulation.

pulse reply—The transmission of a pulse or pulse mode by a transponder as the result of an interrogation.

pulse resolution—The minimum time separation, usually in microseconds or milliseconds, between input pulses that permits proper circuit or component response.

pulse rise time—The interval of time required for the leading edge of a pulse to rise from 10 percent to 90 percent of its peak amplitude, unless some other percentage is stated.

pulse sample-and-hold circuit—A circuit that holds the final amplitude of an integrated pulse until the final amplitude of the succeeding integrated pulse is reached. A less desirable sample-and-hold circuit resets after each hold period to a fixed level before integrating a succeeding pulse.

pulse scaler—A device capable of producing an output signal whenever a prescribed number of input pulses has been received. It frequently includes indicating devices that facilitate interpolation.

Pulse modulation, 3.

pulse selector—A circuit or device that selects the proper pulse from a sequence of (telemetering) pulses.

pulse separation—The interval between the trailing-edge pulse time of a pulse and the leading-edge pulse time of the succeeding pulse.

pulse shaper—Any transducer (including pulse regenerators) used for changing one or more characteristics of a pulse.

pulse shaping—Intentionally changing the shape of a pulse.

pulse soldering—Soldering a connection by melting the solder in the joint area by pulsing current through a high-resistance point applied to the joint area and the solder.

pulse spacing—The time interval from one pulse to the next—i.e., between the corresponding times of two consecutive pulses. (The term *pulse interval* for this concept is ambiguous—it may be taken to mean the duration of a pulse instead of the space or interval between pulses.)

pulse-spacing modulation—Formerly called pulse-interval modulation. A form of pulse-time modulation in which the pulse spacing is varied.

pulse spectrum—Also called pulse-frequency spectrum. The frequency distribution, in relative amplitude and phase, of the sinusoidal components of a pulse.

pulse spike—A relatively short-duration pulse superimposed on the main pulse.

pulse-spike amplitude—The peak amplitude of a pulse spike.

pulse spreading—1. The cumulative effect of material and modal dispersions in an optical fiber. 2. See dispersion, 7.

pulse stepper—A stepper motor that responds directly to a pulse of specified length and amplitude. The positioning of the motor shaft is directly proportionate to the number of pulses applied. Rotational direction is controlled by electrical shading.

pulse-storage time—The time interval from a point at 90 percent of the maximum amplitude on the trailing edge of the input pulse to the same 90-percent point on the trailing edge of the output pulse.

pulse stretcher—1. A circuit designed to extend the duration of a pulse—primarily so that its pulse modulation will be more readily discernible in an audio presentation. 2. In a computer, a circuit that generates a long pulse when triggered by a short pulse. The width of the output pulse is determined by the value of the coupling capacitor. The maximum width of the output pulse cannot exceed 50 percent of the clock rate.

pulse tilt—A distortion characterized in an otherwise essentially flat-topped rectangular pulse by either a decline or a rise of the pulse top.

pulse time—The time interval from a point at 90 percent of the maximum amplitude on the leading edge of a pulse to the 90-percent point on the trailing edge.

pulse-time-modulated radiosonde—Also called time-interval radiosonde. A radiosonde that transmits the indications of the meteorological sensing elements in the form of pulses spaced in time. The meteorological data is evaluated from the intervals between the pulses.

pulse-time modulation—Abbreviated PTM. Modulation (e.g., pulse-duration and pulse-position) in which the values of instantaneous samples of the modulating wave are made to modulate the occurrence time of some characteristic of a pulse carrier.

pulse timer—A timer whose time cycle is started with a continuous input voltage and application or removal of an additional positive input voltage pulse. At the end of the time-delay period, the contacts transfer.

pulse train—Also called pulse group or impulse train. 1. A group or sequence of pulses of similar characteristics. 2. A succession of pulses, usually at equal intervals.

pulse-train frequency spectrum—See pulse-train spectrum.

pulse-train spectrum—Also called pulse-train frequency spectrum. The frequency distribution, in amplitude and in phase angle, of the sinusoidal components of the pulse train.

pulse transformer—1. A special type of transformer designed to pass pulse waveforms as distinguished from sine waves. The major features of a pulse transformer are high-voltage insulation between windings and to ground, low capacitance between windings, and low reactance in the windings. 2. A transformer capable of passing a wide band of frequencies; thus, it can pass a pulse with minimal distortion.

Pulse transformer.

pulse transmitter—1. A pulse-modulated transmitter in which the peak power-output capabilities are usually larger than the average power-output rating. 2. A transmitter used to generate and transmit pulses over a telemetering or pilot-wire circuit to the remote indicating or receiving device.

pulse-triggered binary—A flip-flop in which a change of state results from application of a pulse or waveform of short duration to the input.

pulse valley—See pulse duration.

pulse width—In a pulse, the portion between two specified maxima.

pulse-width discriminator—A device that measures the pulse length of video signals and passes only those whose time duration falls into some predetermined design tolerance.

pulse-width modulation—See pulse-duration modulation.

pulse-width modulation/frequency modulation—See pulse-duration modulation/frequency modulation.

pulse-width modulator amplifier—See class D amplifier.

pulsing key—1. A method of transmitting voice-frequency pulses over a line under control of a key at the original office. It is used with E and M supervision in intertoll dialing. 2. A system of signaling in which numbered keys are used instead of a dial.

pulsing transformer—A transformer designed to supply pulses of voltage or current.

pump—1. An external source used to increase the electron population of excited energy states. 2. Of a parametric device, the source of alternating-current power that causes the nonlinear reactor to behave as a time-varying reactance. 3. To supply high-frequency energy to a maser, laser, parametric amplifier, etc.

pumped tube—An electron tube (chiefly a pool cathode) that is continuously connected to evacuating equipment during operation.

pumping—Of a laser, the application of radiation of appropriate frequency to invert the distribution of systems of electrons of the laser media so that the levels of higher-energy states are more populated.

pumping band—A group of energy states to which ions in the ground state are excited at first when pumping radiation is applied to a laser medium. The pumping band usually is higher in energy than the levels that are to be inverted.

pumping frequency—The frequency at which pumping is provided in a maser, quadrupole amplifier, or other amplifier requiring high-frequency excitation.

pumping radiation—Light applied to the sides or end of a laser crystal for excitation of the ions to the pumping band.

pump oscillator—An alternating-current generator that supplies pumping energy for maser and parametric amplifiers. Operates at twice or some higher multiple of the signal frequency.

punch-card machine—*See* key punch.

punched card—A heavy, stiff paper of constant size and shape, suitable for punching in a pattern that has meaning and for being handled mechanically. The punched holes are sensed electrically by wire brushes, mechanically by metal fingers, or photoelectrically by photocells. The standard card measures $3\frac{1}{4} \times 7\frac{3}{8}$ inches (8.25 \times 18.73 cm) and contains 80 columns and 12 rows in which information may be punched. 2. A piece of lightweight cardboard on which information is represented by holes punched in specific positions.

punched tape—Also called tape, perforated tape, or punched paper tape. Paper tape punched in a coded pattern of holes, which convey information.

punched-tape recorder—A recorder that records data in the form of holes punched in a tape strip.

punch-through—1. A permanently destructive short circuit through the thin dielectric insulator located between the gate and substrate in a metal-oxide semiconductor device. 2. A disruptive discharge through a dielectric layer in a semiconductor caused by the application of an excessive electric field.

punch-through voltage—1. That voltage at which two adjacent diffused transistor beds become shorted together, causing a sharp rise in current. 2. The value of the collector-base voltage of a transistor, above which the open-circuit emitter-base voltage increases almost linearly with increasing collector-base voltage. (Reach-through voltage is a term also used in the United States.) 3. A form of transistor failure in which an internal short develops between emitter and collector across the base, usually as a result of excessive voltages.

puncture—1. A disruptive discharge of current through insulation, which breaks down under electrostatic stress and permits the flow of a sudden large current through the opening. *See also* breakdown. 2. Breakdown of a solid dielectric or insulation, frequently resulting in a hole.

puncture voltage—The voltage at which insulation fails by disruptive discharge through the insulation sample. It is assumed that the sample area is large enough to prevent flashover.

Pupin coil—An iron-core loading coil inserted into telephone lines at regular intervals to balance out the effect of capacitance between the lines.

pup jack—*See* tip jack.

pure code—Another term for reentrant code. Code that is never modified in the process of execution. Hence, it is possible to let many users share the same copy of a program.

pure tone—*See* simple tone, 2.

purity—Physically complete saturation of a hue—i.e., uncontaminated by white and other colors. *See also* excitation purity.

purity coil—1. A coil consisting of two current-carrying windings. In a color television receiver, they produce a magnetic field that directs the three electron beams so that each one will strike only the proper set of phosphor dots. 2. An electromagnetic device placed about the neck of a three-gun tricolor picture tube. Its function is to control the angle at which all three beams approach the aperture mask. Its correct adjustment produces pure colors of red, green, and blue on the phosphor-dot faceplate.

purity control—A variable resistor that controls the current through the purity coil mounted around the neck of a color picture tube.

purity magnet—Two adjustable magnetic rings used in place of a purity coil.

Purkinje effect—As ambient lighting is dimmed, the response of the eye shifts away from the red region and toward the blue region of the color spectrum. Maximum response then tends toward blue-green, rather than the yellow-green maxima of bright daylight.

purple boundary—The straight line drawn between the ends of the spectrum locus on a chromaticity diagram.

purple plague—1. A compound that forms as a result of intimate contact between gold and aluminum, and appears on silicon planar devices and integrated circuits in which gold leads are bonded to aluminum thin-film contacts and interconnections. It causes serious degradation of the reliability of semiconductor devices. 2. An intermetallic gold-aluminum compound formed when gold wires are bonded to aluminum bonding pads. As the compound forms, aluminum migrates from the bonding pad until depleted, and the bond ultimately fails. The name stems from the deep purple color associated with the compound. 3. The tendency of a gold-to-aluminum wire junction to develop a small electrical potential, especially in the presence of moisture. It thus becomes a small battery, which encourages a migration of aluminum molecules toward the gold. The subsequent dark growth on the gold side of the bond—AlAu, “the purple plague”—is believed to raise the contact resistance and weaken the strength of the gold-aluminum junction. 4. One of the several gold-aluminum compounds formed when bonding gold to aluminum; activated by reexposure to moisture and high temperature (>340°C). Purple plague is purplish in color and is very brittle, potentially leading to time-based failure of the bonds. Its growth is highly enhanced by the presence of silicon to form ternary compounds.

PUSH—1. A computer instruction used to deposit a word on top of the stack. 2. (*Lowercase*) Storing a byte of data on the data stack.

pushback hookup wire—Tinned copper wire covered with loosely braided insulation, which can be pushed back with the fingers to expose enough bare wire for making a connection.

push button—Device mounted on a plunger (or actuator) that interfaces the operator's fingertip with the internal mechanism of the switch.

push-button control—Control of equipment by means of push buttons, which in turn operate relays, etc.

push-button dialing—The use of keys or push buttons to generate a sequence of digits to establish a telephone circuit connection.

push-button dialing pad—A twelve-key device for originating tone keying signals. Usually, it is attached to a rotary-dial telephone for origination of data signals.

push-button switch—A switch in which a button must be depressed each time the contacts are to be opened or closed.

push-button tuner—A series of push-button switches that connect into a circuit, with the correct tuning frequency corresponding to the depressed button.

pushdown dialing—Also called tone dialing and touch call. The use of keys or push buttons instead of a rotary dial to generate a signal, usually in the form of tones, representing a sequence of digits and used to set up a circuit connection.

pushdown list—1. A list that is made up and maintained in such a way that the next item to be retrieved is the item most recently stored (last in, first out). 2. An alternative name for a stack.

pushdown stack—Also called P-stack. 1. A circuit that operates in the reverse of a shift register. Whereas, a shift register is a first-in first-out (FIFO) circuit, pushdown stacks are last-in, first-out (LIFO) memories. When data is requested, the stack will read the last data stored, and all other data will move one step closer to the output. Unless memory is emptied, the first data in will never be retrieved. 2. A register that receives information from the program counter and stores the address locations of the instructions that have been pushed down during an interrupt. This stack can be used for subroutines. Its size determines the level of subroutine nesting (one less than its size, or 15 levels of subroutine nesting in a 16-word register). When instructions are returned they are popped back on a last-in, first-out (LIFO) basis. 3. Dedicated consecutive temporary storage registers in a computer, sometimes part of system memory, structured so that the data items retrieved are the most recent items stored on the stack. *See* LIFO. 4. Essentially a last-in, first-out buffer. As data is added, the stack moves down with the last item, added taking the top position. Stack height varies with the number of stored items, increasing or decreasing with the entering or retrieving of data. The words push (move down) and pop (retrieve the most recently stoked item) are used to describe its operation. In actual practice, a hardware-implemented pushdown stack is a collection of registers with a counter that serves as a pointer to indicate the most recently loaded register. Registers are unloaded in the reverse of the sequence in which they were loaded.

pushdown stack architecture—An organization of memory technique for overcoming certain minicomputer limitations. It provides the high storage efficiency of assembly-language programs while sacrificing little of the simplicity and lower software cost of using higher-level languages. Pushdown stack architecture greatly simplifies the work of the high-level language compiler. *See* pushdown stack.

pushing figure—The change in oscillator frequency due to a specified change in plate current (excluding thermal effects).

push-off strength—The amount of force required to dislodge a chip device from its mounting pad by application of the force to one side of the device, parallel to the mounting surface.

push operation—Refers to the storing of operand(s) from a general register(s) into the most current top location in a pushdown memory stack. *See also* stack.

push-pull amplifier—*See* balanced amplifier.

push-pull circuit—A circuit containing two like elements that operate in 180° phase relationship to produce additive output components of the desired wave and cancellation of certain unwanted products. Push-pull amplifiers and oscillators use such a circuit.

push-pull configuration—A fundamental oscillator design in which each half of the circuit operates during a portion of the rf cycle. Primary advantages are increased power output over a single or parallel pair of transistors or tubes and reduction of second harmonic content in the output.

push-pull currents—Balanced currents.

push-pull doubler—An amplifier used for frequency doubling. It consists of two transistors or vacuum tubes; the latter have their grids (input) connected in push-pull configuration and their plates (output) in push-pull or parallel configuration.

push-pull microphone—A microphone comprising two like elements actuated by the same sound waves and operated 180° out of phase.

push-pull oscillator—A balanced oscillator employing two similar tubes or transistors in phase opposition.

push-pull transformer—An audio-frequency transformer that has a center-tapped winding and is used in a push-pull amplifier circuit.

push-pull voltages—Balanced voltages.

push-push circuit—A circuit usually used as a frequency multiplier to emphasize even-order harmonics. Two similar transistors are employed, or two tubes with their grids connected in phase opposition and their plates in parallel to a common load.

push-push configuration—A harmonic oscillator design in which the signals from each output transistor or tube operating at f_o are combined to produce an output signal at $2f_o$. The main advantage of this configuration is the extension of transistor operating frequency limits without the use of an extra frequency-doubler circuit.

push-push currents—Currents that are equal in magnitude and that flow in the same direction at every point in the two conductors of a balanced line.

push-push voltages—Voltages that are equal in magnitude and have the same polarity (relative to ground) at every point on the two conductors of a balanced line.

push rod—A shaft that connects a servo or other actuator with a part of the controlled device.

push-to-talk switch—*See* press-to-talk switch.

pushup list—A list that is made up and maintained in such a way that the next item to be retrieved and removed is the oldest item remaining in the list (first in, first out).

PUT—Abbreviation for programmable unijunction transistor.

PUT.

put — To insert a single data record into an output file.

PVC — Abbreviation for polyvinyl chloride.

pW — Letter symbol for picowatt.

PWM — Abbreviation for pulse-width modulator. 1. A digital logic circuit that can be programmed to produce pulses having any desired period or duty cycle. A means of controlling variable-speed motors. 2. A form of analog control in which the duration of digital pulses is varied analogously with the signal of interest.

PWM/FM — A system in which a number of pulse-width-modulated subcarriers are used to frequency modulate the carrier.

pylon antenna — A vertical antenna constructed of one or more sheet-metal cylinders with a lengthwise slot. The gain depends on the number of sections.

pyramidal horn — An electromagnetic horn whose sides form a pyramid. The electromagnetic field in such a horn would be expressed basically in a family of spherical coordinates.

pyramid wave — A triangular wave whose sides are approximately equal in length.

pyroelectric effect — Also called pyroelectricity. The redistribution of the charge in a crystal that has been heated. The crystal is left with a net electric dipole moment — i.e., the centers of the positive and negative charges are separated.

pyroelectric infrared detector — A current source with an output proportional to the rate of change of its temperature. Widely used in radiometric systems, from industrial temperature-measuring systems to environmental satellite instruments to the analysis of infrared lasers.

pyroelectricity — See pyroelectric effect.

pyroelectric material — A material that produces electrical output when subjected to a change in temperature.

pyroelectric pulse detector — A current-source thermal detector used to detect and study the pulses obtained from particular lasers.

pyroheliometer — A device for the measurement of infrared radiation.

pyrolysis — The thermal decomposition of a volatile chemical compound into nonvolatile and volatile byproducts. It is generally carried out in an inert carrier gas, and this fact distinguishes it from vapor plating.

pyromagnetic — Pertaining to the effect of heat and magnetism on each other.

pyrometer — 1. An instrument used to measure elevated temperatures (beyond the range of mercury thermometers) by electric means. These include immersion optical, radiation, resistance, and thermoelectric pyrometers. 2. A temperature-measuring instrument incorporating a sensor and a readout device.

pyrone detector — A crystal detector in which rectification occurs between iron pyrites and copper (or other metallic points).

pyrotechnic — Pertaining to explosive-actuated devices, especially those that burn rather than producing a shattering effect.

Pythagorean scale — A musical scale in which the frequency intervals are represented by the ratios of integral powers of 2 and 3.

Q

Q—1. Also called quality factor or Q factor. A measure of the relationship between stored energy and rate of dissipation in certain electric elements, structures, or materials. In an inductor or capacitor, the ratio of its reactance to its effective series resistance at a given frequency. 2. A measure of the sharpness of resonance or frequency selectivity of a mechanical or electrical system. 3. Figure of merit for energy-storing device, tuned circuit, or resonant system. 4. Half-width of power spectrum of bandpass filter response in hertz divided by the center frequency in hertz. 5. The figure of merit of a resonator, defined as twice the average energy stored in the resonator divided by the energy dissipated per cycle. The higher the reflectivity of the surfaces of an optical resonator, the higher the Q and the less energy loss from the desired mode. 6. Symbol for quantity of electric charge.

QAM—Abbreviation for quadrature amplitude modulation. A high-speed modem modulation technique employing both differential phase modulation and amplitude modulation.

Q antenna—A dipole matched to its transmission line by stub matching.

Q band—A band of frequencies extending from 36 to 46 GHz, corresponding to wavelengths of 0.834 to 0.652 cm.

Q (Q-bar) output—The second output of a flip-flop; its logic level is always opposite to that of the Q output.

Q channel—The 0.5-MHz-wide band used in the American NTSC color television system to transmit green-magenta color information.

QCW—A 3.58-MHz continuous-wave signal having Q phase. The term is generally limited to refer to the color-television receiver local oscillator and associated circuits.

QCW signal—See quadrature-phase subcarrier signal.

Q demodulator—A demodulator circuit whose inputs are the chrominance signal and the signal from the local 3.58-MHz oscillator after it has been shifted 90°. This phase shift is necessary so that the local signal will be an accurate representation of the Q subcarrier that was suppressed at the transmitter. The output of the Q demodulator is a color video signal representing colors in the televised scene.

q8—A quadrasonic eight-track tape cartridge.

Q-8—Formerly known as Quad-8; term applied to tape cartridges when they contain four-channel programming.

Q factor—1. Of a tuned circuit, the ratio of the inductive reactance of the circuit at the resonant frequency to its radio-frequency resistance. It is a measure of the increase in voltage that is developed across the tuned circuit at resonant frequency, and so the term "magnification factor" is sometimes used for Q . If the Q factor of a tuned circuit is high, the voltages developed across it are high and its selectivity is good. 2. See Q , 1.

Q-meter—Also called a quality-factor meter. An instrument for measuring the Q , or quality factor, of a circuit or circuit element.

Q-multiplier—A special filter that has a sharply peaked response curve or a deep rejection notch at a particular frequency.

Q output—The reference output of a flip-flop. That is, the flip-flop is said to be in the 1 state when this output is 1, and it is said to be in the 0 state when this output is 0.

Q-phase—Also called quadrature carrier. A color-television signal carrier having a phase difference of 147° from the color subcarrier.

QPL—Abbreviation for qualified products list. Military qualified products list for high-reliability applications.

QRM—An obsolete term for any type of man-made interference.

QRS complex—That portion of the waveform in an electrocardiogram extending from point Q to point S; it includes the maximum amplitude shown in the trace.

QS—A matrix system developed by Sansui Electronics.

Q signal—1. In color television, the signal formed by the combination of R-Y and B-Y color-difference signals having positive polarities of 0.48 and 0.41, respectively. It is one of the two signals used to modulate the chrominance subcarrier, the other being the I signal. See also coarse-chrominance primary. 2. In a color TV system, the color sidebands produced by modulating the color subcarrier at a phase 147° removed from the burst reference phase (sometimes known as the quadrature signal). This signal is capable of reproducing the range of colors from purple to yellow-green. 3. One of a special group of abbreviations used in radiocommunications.

QSL—1. Written acknowledgement of two-way radio-communication. 2. A card or letter from a station used to confirm listener's reception reports. A QSL, or verification, confirms that a listener's report was correct. Often a colorful, well-designed postcard. Also exchanged by radio amateurs to confirm contacts with each other.

QSL card—A card exchanged by radio amateurs to confirm radiocommunications with each other.

Q-switch—A device used to rapidly change the Q of an optical resonator. Used in the optical resonator of a laser to prevent lasing action until the high level of inversion (optical gain and energy storage) is achieved in the laser rod. A giant pulse is generated when the switch rapidly increases the Q of the cavity.

Q-switched laser—A laser in which the Q of the resonant cavity is spoiled, using rotating mirrors or saturable absorbers, until large quantities of energy are accumulated in the active medium. Return of the Q causes a high-energy short pulse.

Q-switched pulse—The output of a laser when the Q of the cavity resonator initially is kept very low so that the population inversion achieved is much larger

than that which normally characterizes laser operation. On restoration of the Q to its normal high value, a high-power, short-duration pulse of coherent radiation (called a giant pulse) is emitted. Used most often in conjunction with pulsed pump radiation.

quad—1. A structural unit employed in cables. A quad consists of four separately insulated conductors twisted together. These conductors may take the form of two twisted pairs. 2. A combination of four elements, either electronic components or complete circuits, in series-parallel or parallel-series arrangement. 3. A (series-parallel) combination of four transistors. 4. *See* quadraphonic.

quadded cable—A cable in which some or all of the conductors are in the form of quads.

quadding—Connecting transistors in a series-parallel configuration to achieve greater reliability.

Quad-8—*See* Q-8.

quad latch—A group of four flip-flops, each of which has the capability of storing a true or false logic level, and all of which normally are enabled by a single control line. When the flip-flops are all enabled new information may be stored in each of them.

quadradisc—Another name for CD-4 disc.

quadrant—1. A sector, arc, or angle of 90° . 2. An instrument for measuring or setting vertical angles.

quadrantal error—The error in magnetic-compass readings by the magnetic field of the steel hull of a ship, or by metal structures near the loop antenna of radio direction finders aboard a vessel or aircraft.

quadrant electrometer—An electrometer for measuring voltages and charges by means of electrostatic forces. A metal plate or needle is suspended horizontally inside a vertical metal cylinder that is divided into four insulated parts, each connected electrically to the one opposite it. The two parts of quadrants are connected to the two terminals between which the potential difference is to be measured. The resultant electrostatic forces displace the suspended indicator a certain amount, depending on the voltage.

quadraphonic—Also spelled quadriphonic, quadrasonic; sometimes contracted to quad. A term used to describe four-channel sound systems and equipment. Sounds recorded and reproduced from four different directions to produce a field of sounds coming from an apparent 360° around the listener. Generally, any system of sound reproduction using more than the two usual stereo signals to recreate an impression of sounds coming from the rear of the listener as well as from the front.

quadrphony—A scheme of extended stereo whereby ambient and dimensional information is fed directly or

via a matrix to a set of four speaker systems suitably oriented in the listening room. Various modulation or matrix systems are sometimes used so that four channels can be obtained by using some two-channel (stereo) equipment. The signals are then decoded so that four channels of sound can be reproduced through four speakers.

quadrasonic—*See* quadraphonic.

quadratic programming—In operations research, a particular case of nonlinear programming in which the function to be maximized or minimized and the constraints are quadratic functions of the controllable variables.

quadrature—The state or condition of two related periodic functions or two related points separated by a quarter of a cycle, or 90 electrical degrees.

quadrature amplifier—A stage used to supply two signals of the same frequency but with phase angles that differ by 90 electrical degrees.

quadrature amplitude modulation—*See* QAM.

quadrature carrier—*See* Q-phase.

quadrature component—1. The reactive current or voltage component due to inductive or capacitive reactance in a circuit. 2. A vector representing an alternating quantity that is in quadrature (at 90°) with some reference vector.

quadrature modulation—The modulation of two carrier components 90° apart in phase by separate modulating functions.

quadrature phase detector—A phase detector operated in quadrature (90° out of phase) with the loop detector.

quadrature-phase subcarrier signal—Abbreviated QCW signal. That portion of the chrominance signal that leads or lags the in-phase portion by 90° .

quadrature portion—In the chrominance signal, the portion with the same or opposite phase from that of the subcarrier modulated by the Q signal. This portion of the chrominance signal may lead or lag the in-phase portion by 90 electrical degrees.

quadrature sensitivity—Also called side sensitivity, lateral sensitivity, or crosstalk sensitivity. The sensitivity of a transducer to motion normal to the principal axis. Commonly expressed in percent of the sensitivity in the principal axis.

quadriphonic—*See* quadraphonic.

quadrupole network—*See* two-terminal-pair network.

quadruple diversity—The operation of combining four identical signals received over diverse paths to obtain an improvement of up to 6 dB in signal-to-noise ratio.

quadruple-diversity system—A receiving system in which space-diversity and frequency-diversity techniques are employed simultaneously.

quadruple play—Magnetic recording tape that is thinner than standard-play tape and consequently makes possible recordings four times longer than the standard-play tape.

quadruplex circuit—A telegraph circuit designed for carrying two messages in each direction simultaneously.

quadrupole—A combination of two dipoles that produces a force varying in inverse proportion to the fourth power of the distance from the generating charge.

quadrupole network—*See* two-terminal-pair network.

qualification—The entire procedure by which electronic parts are examined and tested to obtain and maintain approval at specified failure rate levels, and then identified on the qualified products lists.

qualified products list—Abbreviated QPL. A listing of manufacturers qualified by test and performance

Quadraphony.

verification to produce items listed in the military specifications.

qualifying activity—The military activity or its agent delegated to administer the qualification program.

qualitative analysis—A study that reveals how a system works.

quality—1. The extent of conformance to specifications of a device, or the proportion of satisfactory devices in a lot. 2. The extent to which a device meets the required specifications when it is shipped to the user.

quality assurance—1. A planned, systematic pattern of actions necessary to provide suitable confidence that a system or component will perform satisfactorily in actual operation. 2. A systematic pattern of actions throughout design and production, to ensure confidence in a product's conformance with specifications.

quality control—The control of variation of workmanship, processes, and materials in order to produce a consistent, uniform product.

quality engineering—An engineering program whose purposes are to establish suitable quality tests and quality acceptance criteria and to interpret quality data.

quality factor—See *Q*, 1.

quality-factor meter—See *Q*-meter.

quantitative analysis—A study that determines how well a system performs.

quantity—1. Any positive or negative number. It may be a whole number, a fraction, or a whole number and a fraction. 2. A constant, variable, function name, or expression. 3. In computers, a positive or negative real number; the term *quantity* is preferred to the term *number*.

quantity of electricity—See electrical charge.

quantization—1. The process whereby the range of values of a wave is divided into a finite number of subranges, each represented by an assigned (quantized) value. 2. The process of converting a continuous analog input into a set of discrete output levels.

quantization distortion—Also called quantization noise. Inherent distortion introduced during quantization.

quantization error—1. The difference between the actual values of data and corresponding discrete values resulting from quantization. 2. Error generated because an analog-to-digital converter can be no more accurate than $\pm 1/2$ lsb because of its resolution.

quantization level—1. A particular subrange in quantization. 2. The symbol designating the subrange of (1).

quantization noise—See quantization distortion.

quantize—1. To convert a continuous variable, such as a waveform, into a series of levels or steps. There are no in-between values in such a quantized waveform. All values of signal are represented by the nearest standard of value or code position. 2. To sample the amplitudes of a complex wave periodically, and to represent each amplitude thus sampled by one of a finite number of values. 3. To restrict a variable to a discrete number of possible values.

quantized pulse modulation—Pulse modulation that involves quantization (e.g., pulse numbers modulation or pulse code modulation).

quantizer—1. A device that partitions a continuum of analog values into discrete ranges to be represented by a digital code. An analog-to-digital converter. 2. A device with a restricted quantity of possible output values that will assimilate any range of input values into its limited range.

quantizing—Expressing an analog value as the nearest one of a discrete set of prechosen values.

quantizing error—1. The basic uncertainty associated with digitizing an analog signal, due to the finite resolution of an a/d converter. An ideal converter has a maximum quantizing error of $\pm 1/2$ lsb. In an a/c converter, an infinite number of possible input voltages can occur, but only 2^n output codes (n = number of bits) can exist. Because of this quantizing effect, there will always be an error as great as $1/2$ lsb, and the greatest error will occur in the value of the transition voltage at the point where the output changes state. 2. A measure of the ability of a digital meter to discriminate between an incremental value and values slightly above or below this value. 3. An error caused by conversion of a variable having a continuous range of values to a quantized form having only discrete values, as in analog-to-digital conversion. The error is the difference between the original (analog) value and its quantized (digital) representation.

quantum—1. A discrete portion of energy of a definite amount. It was first associated with intra-atomic or intermolecular processes involving changes among electrons, and the corresponding radiation. 2. If the magnitude of a quantity is always an integral multiple of a definite unit, then that unit is called the quantum of the quantity. 3. The angular increment of input-shaft rotation of an encoder, subtended by one code position. 4. The unit carrier of energy: the photon for light, and the electron for electricity. 5. The smallest amount into which the energy of a wave can be divided. The quantum is proportional to the frequency of the wave. See photon.

quantum efficiency—1. In a phototube, the average number of electrons photoelectrically emitted from the photocathode per incident photon of a given wavelength. 2. The fraction of those ions or atoms excited to a higher energy level by pumping radiation that decays with light emission in a particular desired range of frequencies. The remaining ions decay by various radiationless mechanisms (such as phonon emission) or by undesired radiative transitions. 3. The ratio of the number of carriers generated to the number of photons incident upon the active region. 4. The ratio of the number of quanta radiant energy (photons) emitted per second to the number of electrons flowing per second, e.g., photons/electrons. 5. Ratio of generated current carriers to the number of absorbed photons.

quantum-limited operation—In the operation of a photodetector, the inability of the detector to measure incident radiation levels below a threshold level because of fluctuations in the output current that are not due to incident radiation, i.e., not due to incident photons.

quantum mechanics—1. The study of atomic structure and other related problems in terms of quantities that can actually be measured. 2. The science of all complex elements of atomic and molecular spectra, and the interaction of radiation and matter.

quantum noise—1. A random variation or noise signal due to fluctuations in the average rate of incidence of quanta on a detector. The basic electromagnetic quantum of noise power is just 1 photon per electromagnetic mode. 2. Noise generated within an optical communications system link that has both internal (dark current) and external (background noise, noise in signal) components.

quantum number—Any set of numbers assigned to the particular values of a quantized quantity in its discrete range. The state of a particle or system may be described by a set of compatible quantum numbers.

quantum theory—The theory that an atom or molecule does not emit or absorb energy continuously. Rather, it does so in a series of steps, each step being the emission or absorption of an amount of energy called

the quantum. The energy in each quantum is directly proportionate to the frequency.

quantum transition—A transition between two quantum states.

quarter phase—See two-phase.

quarter-squares multiplier—An analog multiplier unit that makes use of the relationship $xy = \frac{1}{4}[(x + y)^2 - (x - y)^2]$.

quarter track—See four-track.

quarter-track tape—See four-track tape.

quarter wave—One-quarter cycle of a wave.

quarter-wave antenna—1. An antenna whose electrical length is one-quarter the wavelength of the transmitted or received signal. 2. A dipole antenna with an electrical length equal to one-quarter of its working wavelength. Its physical length is somewhat shorter than one-quarter wavelength.

quarter-wave attenuator—Two energy-absorbing grids or other structures placed in a transmission line and separated by an odd number of quarter wavelengths. As a result, the wave reflected from the first grid annuls the wave reflected from the second grid.

quarter-wavelength—That distance which corresponds to an electrical length of a quarter of a wavelength of the frequency under consideration.

quarter-wave line—See quarter-wave stub.

quarter-wave plate—A mica or other double-refracting crystal plate of such thickness that a phase difference of one-quarter cycle is introduced between the ordinary and extraordinary components of light passing through.

quarter-wave resonance—In a quarter-wave antenna, the condition in which its resonant frequency is equal to the frequency at which it is to be used.

quarter-wave stub—Also called a quarter-wave line or quarter-wave transmission line. A section of transmission line equal to one-quarter of a wavelength at the fundamental frequency. It is commonly used to suppress even harmonics. This is done by shorting the far end so that the open end presents a high impedance to the fundamental frequency and all odd harmonics, but not to the even-order harmonics.

Quarter-wave stub.

quarter-wave support—A quarter-wave metallic stub used in place of dielectric insulators between the inner and outer conductors of a coaxial transmission line.

Quarter-wave supports.

quarter-wave termination—A waveguide termination consisting of a metal plate and a wire grating (or semiconducting film) spaced one-quarter wavelength apart. The plate is the terminating element. The wave reflected by the grating (or film) is cancelled by the wave reflected by the plate.

quarter-wave transformer—A one-quarter-wavelength section of transmission line used for impedance matching.

quarter-wave transmission line—See quarter-wave stub.

quartz—A mineral (silicon dioxide) occurring in hexagonal crystals in nature and having piezoelectric properties that are highly useful in radio and carrier communication. The crystals from which slabs are cut for oscillators are transparent and almost colorless. When excited electrically, they vibrate and maintain extremely accurate and stable frequencies.

quartz crystal—Also called a crystal. 1. A thin slab cut from quartz and ground to the thickness at which it will vibrate at the desired frequency when supplied with energy. It is used to accurately control the frequency of an oscillator. 2. The naturally occurring crystalline form of silicon dioxide. It is slightly birefringent and exhibits rotary dispersion of light rays transmitted along the crystal axis, both right-hand and left-hand forms being known. Quartz transmits light from about 0.18 to 4.5 micrometers in the infrared. It is very hard and takes a high polish, and has a low thermal expansion coefficient. 3. A piezoelectrical crystal cut from natural quartz (silicon dioxide, SiO_2).

quartz delay line—A delay line in which fused quartz is the medium for delaying sound transmission or a train of waves.

quartz lamp—A mercury-vapor lamp having a transparent envelope made from quartz instead of glass. Quartz resists heat (permitting a higher current) and passes ultraviolet rays, which glass will absorb.

quartz light source—A lamp with a quartz bulb that transmits radiation generally rich in ultraviolet.

quartz plate—A crystalline-quartz section completely finished to specifications, with its two major faces essentially parallel.

quartz resonator—A piezoelectric resonator with a quartz plate.

quasi-complementary symmetry circuit—A push-pull power amplifier that utilizes npn output transistors driven by pnp and npn driver transistors.

quasi-linear feedback-control system—A feedback-control system in which the relationships between the pertinent measures of the system input and output signals are substantially linear despite the existence of nonlinear elements.

quasi-monochromatic light—Light radiation that behaves like ideal monochromatic radiation. The frequencies of quasi-monochromatic radiation are strongly peaked about a certain frequency.

quasi-optical — Having properties similar to those of light waves. The propagation of waves in the television spectrum is said to be quasi-optical (i.e., cut off by the horizon).

quasi-random code generator — A high-speed PCM information source that provides a means of closed-loop testing for use in designing and evaluating wideband communications links.

quasi-rectangular wave — A wave nearly, but not quite, rectangular in shape.

quasi-single-sideband transmission — Simulated single-sideband transmission done by transmitting parts of both sidebands.

quasi-steady-state vibration — A nearly periodic vibration in which the amplitude and phase relationships of the component sinusoids vary slowly with time.

quaternary — A coding scheme that uses four different voltage levels to represent information, used over the local loop with basic ISDN.

quaternary signaling — The communications mode in which information is passed by the presence and absence, or plus and minus variations, of four discrete levels of one parameter of the signaling medium.

quench — To stop an oscillation abruptly.

quenched spark — A spark consisting of only a few sharply defined oscillations because the gap is deionized almost immediately after the initial spark has passed.

quenched spark gap — A spark gap with provision for producing a quenched spark. One form consists of many small gaps between electrodes that have a relatively large mass and, thus, are good radiators of heat. As a result, they cool the gaps rapidly and thereby stop conduction.

quenched spark-gap converter — A spark-gap generator or other power source in which the oscillatory discharge of a capacitor through an inductor and a spark gap provides the radio-frequency power. The spark gap comprises one or more closely spaced gaps in series.

quench frequency — 1. An ac voltage applied to an electrode of a tube used as a superregenerative detector to alternately vary its sensitivity and thereby prevent sustained oscillations. The quench frequency is usually lower than the signal frequency to be received. 2. The number of times per second a circuit goes in and out of oscillation.

quenching — 1. The process of terminating a discharge in a radiation-counter tube by inhibiting the re-ignition. 2. A process of rapid cooling from an elevated temperature, in contact with liquids, gases, or solids. 3. The inhibition or elimination of one process by another process. The stimulated emission of a laser oscillator can be quenched by a pulse of radiation of the same frequency traversing the oscillator in a different direction. This pulse induces the excited ions to emit radiation in a direction apart from the oscillating mode and, hence, the oscillation is decreased.

quenching circuit — A circuit that inhibits multiple discharges from an ionizing event by suppressing or reversing the voltage applied to a counter tube.

quenching frequency — That frequency at which oscillations in a superregenerative receiver are suppressed (quenched).

quench oscillator — A superregenerative receiver circuit that produces the quench-frequency signal.

queue — 1. A line of items waiting for service in a system, such as messages to be transmitted in a message-switching system. 2. To arrange in or form a queue. 3. A waiting line for execution of computer or peripheral operations. 4. A multi-element data structure in which the first element in is the first element out.

This data structure works in the same manner as a supermarket checkout line — items are added at one end and removed at the other. Compare with a stack, in which items are added and removed only from one end. 5. An area in the temporary call store memory used to record a writing list for some particular function. For example, the writing list or queue for customer dial pulse receiver circuits. 6. A list of processes to be executed in sequential order, information blocks to be processed in sequential order, or a mixture of the two. 7. Orderly access to a system; generally, “first in, first out” prioritization.

queue control block — A control block for regulating the sequential use of a programmer-defined facility for a number of tasks.

queued access method — An access method that provides automatic synchronization of data transfer between programs using the access method and input/output devices. Delays for input/output operations are thereby eliminated.

queuing theory — A research technique having to do with the correct order of moving units, such as sequence assignments for bits of information, whole messages, assembly-line products, or automobiles in traffic.

quick-break — A characteristic of a switch or circuit breaker, whereby it has a fast contact-opening speed that is independent of the operator.

quick-break fuse — A fuse that draws out the arc and rapidly breaks the circuit when its wire melts. Usually a spring or weight is used to quickly separate the broken ends.

Quick-break fuse.

quick-break switch — A switch that minimizes arcing by breaking a circuit rapidly, independent of the rate at which the switch handle is moved.

quick-connect terminal — 1. A plug-in type of terminal designed to make possible rapid wiring. 2. A type of connection, similar to a lamp plug and wall socket, used where connections are frequently removed, then connected again. Quick-connect terminals are found on home appliances, hi-fi equipment, TV sets, and in other applications.

quick disconnect — A type of connector designed to facilitate rapid locking and unlocking of two contacts or connector halves.

quickening — A characteristic of a display with compressed time scale (such as that employed in time-lapse photography). Used to exaggerate trends.

quick-flashing light — A rhythmic light that shows very quick, regular, alternate displays of light and darkness.

quick-make — A characteristic of a switch or circuit breaker, whereby it has a fast contact-closing speed that is independent of the operator.

quick-make switch — A switch or circuit breaker that has a high contact-closing speed independent of the operator.

quick-stop control — On some tape recorders, and on all recorders used for dictation, a control with which the operator can stop the tape without taking the machine out of the play or record position.

quiescence — 1. The state of a transistor amplifier with no signal applied. 2. The operating condition that exists in a circuit when no input signal is applied to the circuit.

quiescent — At rest; specifically, the condition of a circuit when no input signal is being applied to it.

quiescent-carrier modulation — A modulation system in which the carrier is suppressed during intervals when there is no modulation.

quiescent-carrier telephony — Telephony in which the carrier is suppressed whenever no modulating signals are to be transmitted.

quiescent current — *See* idling current.

quiescent dissipation — The power dissipated by a component or circuit in the absence of dynamic activating signals applied to the input or inputs.

quiescent input voltage — The dc voltage at the input of an amplifier that has one input terminal when that terminal is not connected to any source.

quiescent operating point — 1. The state or condition that exists under any specified external condition when the signal is zero. 2. *See* quiescent point.

quiescent output voltage — The dc voltage at the output terminals of an amplifier when the input is grounded for ac through a resistance equal to the resistance of the signal source.

quiescent period — The resting period; e.g., the period of no activity between pulses in pulse transmissions.

quiescent point — On the characteristic curve of an amplifier, the point representing the conditions existing when there is no input signal. *See also* operating point.

quiescent push-pull — In a radio receiver, a push-pull output stage in which practically no current flows when no signal is being received. Thus, there is no noise while the radio is being tuned between stations.

quiescent state — The time during which a tube or other circuit element is not performing its active function in the circuit.

quiescent value — The voltage or current value of a vacuum-tube electrode when no signals are present.

quiescing — The process of stopping a multiprogrammed system by rejection of new jobs.

quiet automatic volume control — *See* delayed automatic volume control.

quiet AVC — *See* delayed automatic volume control.

quiet battery — Also called talking battery. A source of energy of special design, or with added filters, that is sufficiently quiet and free from interference that it may be used for speech transmission.

quieting — 1. The decrease in noise voltage at the output of an FM receiver in the presence of an unmodulated carrier. 2. A measure of the usable sensitivity of an FM tuner, expressed as the least rf signal level (100 percent modulated with a 400-Hz tone) that reduces the receiver internal noise and distortion to 30 dB below the output level obtained with the modulated tone present $[(s + n)/n = 30 \text{ dB}]$. A null filter tuned to 400 Hz is used to remove the tone. For an AM receiver, the carrier is modulated by 30 percent and the field strength (microvolts per meter) is measured that is necessary to provide a 20 dB $(s + n)/n$ ratio.

quieting sensitivity — In an FM receiver, the minimum input signal that will give a specified output signal-to-noise ratio.

quiet tuning — In a radio receiver, a form of tuning in which the output is silenced except when the receiver is tuned to the precise frequency of the incoming carrier wave.

QWERTY keyboard — The layout on a standard typewriter-style keyboard; the first six letters on the top alphabetic line.

R

R—1. Symbol for resistor, resistance, or reluctance.
2. Letter symbol for roentgen.

race—1. The condition that exists when a signal is propagated through two or more memory elements during the same clock period. 2. The condition that occurs when changing the state of a system requires a change in two or more state variables. If the final state is affected by which variable changes first, the condition is a critical race. 3. An improper condition in which data that is supposed to move in steps, as in a shift register, goes through a whole string of stages at one step. Usually caused by incorrect timing pulses.

raceway—Any channel designed and used solely for holding wires, cables, or bus bars.

rack and panel connector—1. A connector that is attached to a panel or side of equipment so that when these members are brought together, the connector is engaged. 2. A connector that connects the inside back end of the cabinet (rack) with the drawer containing the equipment when it is fully inserted. The drawer permits convenient removal of portions of the equipment for repair or examination. Special design and rugged construction of the connector allows for variations in rack-to-panel alignment.

rack and pinion—A toothed bar (rack) that engages a gear (pinion) to convert the back-and-forth motion of the rack into rotary motion, or the rotary motion of the pinion into back-and-forth motion.

rackmount—Designed to be installed in a cabinet that is usually 19-in. wide.

racon—See radar beacon.

rad—Abbreviation for radiation absorbed dose.
1. The amount of radiation that delivers 100 ergs of energy to 1 gram of a substance. It is approximately equivalent to 1 roentgen in the case of body tissue. 2. The amount of energy transferred to a material by ionizing radiation. One rad is equal to the energy of 100 ergs per gram of material. The material must be specified, because the energy differs with each material.

radar—Acronym for radio detection and ranging. A system that measures distance (and usually the direction) to an object by determining the amount of time required by electromagnetic energy to travel to and return from an object. Called primary radar when the signals are returned by reflection. Called secondary radar when the incident signal triggers a responder beacon and causes it to transmit a second signal. Predicted in the early part of the 20th century, the first important system was built in England in 1938. Basic building blocks of a radar are the transmitter, the antenna (normally used for both transmission and for reception), the receiver, and the data-handling equipment.

radar alarm system—An alarm system that employs radio-frequency motion detectors.

radar altitude—Also called radio altitude. Absolute altitude measured by a radar altimeter.

radar and television aid to navigation—A device that converts a circular-scan radar presentation to a horizontally scanned television presentation. It provides a continuous bright display with target trails for course and speed indications of moving targets.

radar antenna—Any of the many types of antennas used in radar.

Radar antenna.

radar attenuation—Ratio of the transmitted power to the reflected (received) power—specifically, the ratio of the power that the transmitter delivers to the transmission line connected to the transmitting antenna to the power reflected from the target and delivered to the transmission line connected to the receiving antenna.

radar beacon—Also called a racon. An automatic transmitter-receiver that receives signals from a radar transmitter and retransmits coded signals that enable the radar operator to determine his own position.

radar beam—The space where a target can be effectively detected and/or tracked in front of a radar. Its boundary is defined as the locus of points measured radially from the beam center at which the power has decreased to one-half.

radar calibration—Taking measurements on various parts of electronic equipment (e.g., radar, IFF, communications) to determine its performance level.

radar camouflage—The use of coverings or surfaces on an object to considerably reduce the reflected radio energy and, thus, conceal the object from the radar beam.

radar cell—The volume enclosed by dimensions of one radar-pulse length by one radar beamwidth.

radar clutter—The image produced on a radar indicator screen by sea or ground return. If not of particular interest, it tends to obscure the target indication.

radar-confusion reflectors—Metallic devices (e.g., chaff, corner reflections) employed to return false signals in order to confuse enemy radar receivers. The use of radar-confusion reflectors is termed reflective jamming.

radar control area—The designated space within which aircraft approach, holding, stacking, and similar operations are performed under guidance of a surveillance radar system.

radar controller—An air traffic controller or other responsible person proficient in the use and interpretation of radar and capable of performing one or more of the following functions: surveillance controller, traffic director, and final controller.

radar countermeasures—Interception, jamming, deception, and evasion of enemy radar signals to obtain information about the enemy from his radar and to prevent him from obtaining accurate, usable information from his or her radar.

radar-coverage indicator—A device showing how far a radar station should track a given aircraft. It also provides a reference (detection) range for quality control. Aircraft size and altitude, screening angle, site elevation, type of radar, antenna radiation pattern, and antenna tilt are taken into account.

radar cross section—That portion of the backscattering cross section of a target associated with a specified polarization component of the scattered wave.

radar data filtering—A quality-analysis process in which the computer rejects certain radar data and alerts personnel at the mapping and surveillance consoles to the rejection.

radar deception—Radiation or reradiation of radar signals in order to confuse or mislead an enemy operator when he or she interprets the data shown on his or her scope.

radar decoy—An object that has the same reflective characteristics as a target and is used in radar deception.

radar display—The spontaneous visual presentation of radar information by electronic traces on a CRT.

radar distribution switchboard—A switching panel for connecting video, trigger, and bearing from any one of five systems to any or all of 20 repeaters. Also contains order lights, bearing cutouts, alarms, test equipment, etc.

radar dome—A weatherproof cover for protection of a primary radiation element of a radar or radio device; the cover is transparent to radio-frequency energy and permits operation of the radiating element, including rotation or other physical movement. *See also* radome.

radar echo—1. The radio-frequency energy received after it has been reflected from an object. 2. The deflection or change of intensity that a radar echo produces in the display of a cathode-ray tube.

radar equation—A mathematical expression relating the transmitted and received powers and antenna gains of a primary-radar system to the echo area and distance of the target.

radar fence—A network of radar warning stations that maintains constant watch against surprise attack (e.g., the DEW line).

radar field gradient—Abbreviated RFG. The rate at which the strength of the field from a primary radar decreases as the distance from the transmitting antenna increases.

radar frequency bands—The frequency bands for radar are shown in the table.

radargrammetry—The analysis of the photographs taken from the radar display of a survey aircraft and used when recording terrain that is obscured by clouds.

radar homing—Missile guidance for which the intelligence is provided by a radar aboard the missile.

Radar bands

Band	Frequency range
HF	3–30 MHz
VHF	30–300 MHz
UHF	300–1000 MHz
L-band	1.0–2.0 GHz
S-band	2.0–4.0 GHz
C-band	4.0–8.0 GHz
X-band	8.0–12.0 GHz
K _u -band	12.0–18.0 GHz
K-band	18.0–27.0 GHz
K _a -band	27.0–40.0 GHz
millimeter	40–300 GHz

radar horizon—The most distant point (from the radar antenna along a given azimuth) on the earth's surface illuminated by the radar on purely geometric conditions. The conditions are that the illumination occurs along a straight-line path, where the path is taken over an effective earth's radius of 4/3 its true radius and where the illuminating power of the radar is considered unlimited.

radar illumination—The subjection of an object (target) to electromagnetic radiation from a radar.

radar indicator—A cathode-ray tube with its associated equipment that provides a visual indication of the echo signals picked up by the radar set.

radar marker—A fixed facility that continuously emits a radar signal so that a bearing indication appears on a radar display.

radar nautical mile—The time interval of approximately 12.67 microseconds required for radio-frequency energy to travel one nautical mile (1.853 km) and return, a total of two nautical miles.

radar paint—A radar-energy-absorbent material that can be applied to an object to reduce the possibility of detection.

radar-performance figure—Ratio of the pulse power of the radar transmitter to the power of the minimum signal detectable by the receiver.

radar picket—Early-warning aircraft that flies at a distance from a ship or other force being protected, to increase the radar detection range.

radar pulse modulator—A modulator that turns an rf energy source off and on in a precise, known manner. In essence, the modulator supplies the energy that causes an rf source to oscillate or amplify, thus creating a burst, or pulse, of rf energy.

radar range—The maximum range at which a radar can ordinarily detect objects.

radar receiver—The receiver that amplifies the returned radar signal and demodulates the rf carrier before further amplifying the desired signal and delivering it, in a form suitable for presentation, to the indicator. Unlike a radio receiver, it is more sensitive, has a lower noise level, and is designed to pass a pulse signal.

radar-reflection interval—The length of time required for a radar pulse to reach a target and return.

radar reflectivity—A measure of the ability of a radar target to intercept and return a radar signal.

radar relay—1. Equipment for relaying radar video and appropriate synchronizing signals to a remote location. 2. Process or system by which radar echoes and synchronization data are transmitted from a search radar installation to a receiver at a remote point.

radar repeaters—Remote indicators used to reproduce radar data from a primary source.

radar resolution—The ability of a radar to distinguish between the desired target and its surroundings.

radarscope—A cathode-ray tube serving as an oscilloscope, the face of which is the radar viewing screen.

radar selector switch—A manual or motor-driven switch that transfers a plan-position-indicator repeater from one system to another, switching video, trigger, and bearing data.

radar shadow—An area shielded from radar illumination by an intervening reflecting or absorbing medium. This region appears as an area that is void of targets on a radar display.

radar silence—1. A period of time during which radar operations are stopped. 2. An imposed discipline under which the transmission by radar of electromagnetic signals on some or all frequencies is prohibited.

radar speed detector—A broadband, high-sensitivity, rf-level detector. It has a tuned microwave horn antenna that is designed to pass signals in the X- and K- (several thousand megahertz) bands into a diode. The radio-frequency energy is then rectified into a voltage that upsets a delicately balanced alarm circuit. Law enforcement agencies can outwit the detectors. They may use short bursts of radar to monitor specific vehicles momentarily—hardly enough time for a radar detector to resolve whether the incoming signal is a random bit of rf interference or is actually a transmitted radar signal.

radar target—Any reflecting object of particular interest in the path of the radar beam (usually, but not necessarily, the object being tracked).

radar trace—The pattern produced on the screen of the cathode-ray tube in a radar unit.

radar transmitter—The transmitter portion of a radar system. The unit of the radar system in which the rf power is generated and keyed.

radiac—Acronym for radioactive detection, identification, and computation. A descriptive term referring to the detection, identification, and measurement of nuclear radiation.

radiac instrument—*See* radiac set.

radiac meter—*See* radiac set.

radiac set—Also called radiac meter or radiac instrument. Equipment for detecting, identifying, and measuring the intensity of nuclear radiation.

radiac test equipment—Equipment for testing radiac sets.

radial—1. Pertaining to or placed like a radius (i.e., extending or moving outward from a central point, like the spokes of a wagon wheel). 2. One of a number of lines of position defined by an azimuthal navigation facility and identified in terms of its bearing (usually magnetic) from that facility.

radial-beam tube—A vacuum tube producing a flat, radial electron beam that can be rotated about the axis of the tube by an external magnetic field.

radial component—A component that acts along (parallel to) a radius; as contrasted to a tangential component, which acts at right angles (perpendicular) to a radius.

radial component of the electric field—The component of an electric field in the direction of the slant-range vector or the radius vector at which an antenna pattern is measured. The radial component of the electric field is relatively small in the far field and is normally neglected.

radial field—A field of force that is directed toward or away from a point in space.

radial field cathode-ray tube—A CRT in which a fine-grained, curved, high-transmission metallic mesh is placed on the exit side of the deflection area. The mesh establishes a ground plane for the postaccelerating field so that the resulting equipotential surfaces are truly spherical, creating a radial electrostatic field.

radial grating—A conformal grating consisting of wires arranged radially in a circular frame, like the spokes of a wagon wheel. The radial grating is placed inside a circular waveguide to obstruct E waves of zero order, but not the corresponding H waves.

radial lead—A lead extending out the side of a component, rather than from the end. (The latter is called an axial lead.) Some resistors and capacitors have radial leads.

radial tonearm—Sometimes called straight-line tracking arm. A tonearm that moves along a track parallel to the record radius, maintaining perfect tangency to the groove.

radial transmission line—A pair of parallel conducting planes used for propagating uniform cylindrical waves whose axes are normal to the planes.

radian—In a circle, the angle included within an arc equal to the radius of the circle. Numerically it is equal to $57^\circ, 17', 44.8''$. A complete circle contains 2π radians. One radian equals 57.3° , and 1° equals 0.01745 radian.

radiance—Also called emittance. 1. The apparent radiation of a surface. It is the same as luminance except that radiance applies to all kinds of radiation instead of only light flux. 2. Surface radiation. Solid angle times radiant flux per area. 3. The radiant intensity of electromagnetic radiation per unit projected area of a source or other area, i.e., it is the radiant power of electromagnetic radiation per unit solid angle and per unit surface area normal to the direction considered. The surface may be that of a source detector, or it may be any other real or virtual surface intersecting the flux. The unit of measure is watts/steradian-square meter. The concept is usually applicable to the visible or near visible region of the electromagnetic frequency spectrum.

radian frequency—*See* angular velocity.

radial length—The distance, in a sinusoidal wave, between phases differing by an angle of one radian. It is equal to the wavelength divided by 2π .

radian per second—A unit of angular velocity.

radiant—Pertaining to electromagnetic radiation, with the contributions at all wavelengths of interest weighted equally.

radiant efficiency—The ratio of the radiant flux emitted by a source to the power supply.

radiant emittance—The light flux radiated per unit area of a source.

radiant energy—Energy transmitted in the form of electromagnetic radiation (e.g., radio, heat, or light waves). It is measured in units of energy such as kilowatt-hours, ergs, joules, or calories. There is no associated transfer of matter per se under this concept.

radiant-energy detecting device—A device employing radiant energy to detect flaws in the surface and/or volume of solids.

radiant exitance—The radiant power emitted into a full sphere (4π steradians) by a unit area of source.

radiant flux—1. Time rate of flow of radiant energy, expressed in watts or in ergs per second. 2. The radiant energy crossing or striking a surface per unit time, usually measured in watts.

radiant heat—Infrared radiation from a body not hot enough to emit visible radiation.

radiant heater—An electric heating appliance with an exposed incandescent heating element.

radiant intensity—1. The energy emitted within a certain length of time per unit solid angle about the direction considered. 2. The radiant power per unit solid angle in the direction considered, i.e., the time rate of transfer of radiant energy per unit solid angle, or the flux radiated per unit solid angle about the specified direction. The unit of measure is watts per steradian or joules per steradian-second.

radiant power—1. The rate of transfer of radiant energy. 2. The time rate of flow of electromagnetic energy. The unit is watts or joules per second.

radiant reflectance—The ratio of reflected radiant power to incident radiant power.

radiant sensitivity—The output current of a phototube or camera tube divided by the incident radiant flux of a given wavelength at constant electrode voltages. The term "output current" as here used does not include the dark current.

radiant transmittance—The ratio of transmitted radiant power to incident radiant power.

radiate—To emit rays from a center source; e.g., electromagnetic waves emanating from an antenna.

radiated—Energy transfer by propagation of electromagnetic fields.

radiated interference—1. Interference that is transmitted through the atmosphere according to the laws of electromagnetic wave propagation. (The term radiated interference is generally considered to include the transfer of interfering energy by inductive or capacitive coupling.) 2. Any unwanted electrical signal that is radiated from the equipment under test or from any lines connected to that equipment under test.

radiated output noise—Electrical interference signals radiated by switching the ac/dc converters and by the transformer in line-operated power supplies. These signals can cause malfunctioning of analog and digital circuits within their fields.

radiated power—The total energy, in the form of Hertzian waves, radiated from an antenna.

radiated spurious transmitter output—A spurious output radiated from a radio transmitter. (The associated antenna and transmission lines are not considered part of the transmitter.)

radiating curtain—An array of dipoles in a vertical plane, positioned to reinforce each other. Usually placed one-quarter wavelength ahead of a reflecting curtain of corresponding half-wave reflecting antennas.

radiating element—Also called radiator. A basic subdivision of an antenna. It, by itself, is capable of radiating or receiving radio-frequency energy.

radiating guide—A waveguide designed to radiate energy into free space. The waves may emerge through slots or gaps in the guide, or through horns inserted into its wall.

radiation—1. The emission and propagation of energy through space or a material medium. The energy may be in the form of electromagnetic waves (Y-rays and X-rays) or particles (beta particles, alpha particles, and neutrons). 2. A general term for energy emitted from a substance and traveling across space in straight lines. (Originally used only for electromagnetic waves, it now includes streams of particles, such as alpha particles, beta particles, etc.) 3. The transfer of heat from a hot body to a cooler body through space, without heating any medium that may be in the space. 4. The emission of electromagnetic energy into space regardless of the frequency. Thus, radiation includes thermal, radio, visual, and X-ray energy. The propagation of energy by radiation does not require a medium to support transmission. 5. The electromagnetic waves or photons emitted from a source.

6. Act of giving off electromagnetic energy, particularly by an antenna when excited by a transmitter.

radiation angle—The vertical angle at which maximum energy is radiated by an antenna with respect to the earth. Low-angle radiation delivers more energy in the local area. High-angle radiation augments skip transmission and is wasteful of power.

radiation belt—See Van Allen radiation belts.

radiation characteristic—An identifying feature, such as frequency or pulse width, of a radiated signal.

radiation counter—1. A device for counting radiation particles (alpha, beta, gamma, neutrons, etc.) or photons of energy (X-rays, etc.), usually using either scintillation or ionization resulting from the presence of the particle or photon to be measured. 2. An instrument used to recognize and identify incident radiation by the ionizing or stimulating properties of the radiation.

radiation counter tube—See counter tube.

radiation damage—A loss in certain physical properties of organic substances, such as elastomers, caused principally by ionization of the long-chain molecule. This ionization process (i.e., loss of electrons) is believed to result in redundant cross-linking and possible scission of the molecule. The effect is cumulative.

radiation detection (fluorescence)—Radiation detection using fluorescence produced in an efficient screen.

radiation detector—Any of the many devices used to detect the presence of radiation from a specific region of the electromagnetic spectrum.

radiation-detector tube—A tube in which current passes between its electrodes whenever the tube is exposed to penetrating radiation. The amount of this current corresponds to the intensity of radiation.

radiation dosage—The total radiation energy absorbed by a substance, usually expressed in ergs per gram. See also rad; roentgen; roentgen equivalent man; roentgen equivalent physical.

radiation dosimetry—The detection and measurement of the presence of nuclear and X-ray radiation.

radiation efficiency—In an antenna, the ratio of the radiated power to the total power supplied to the antenna at a given frequency.

radiation field—The electromagnetic field that breaks away from a transmitting antenna and radiates outward into space as electromagnetic waves.

radiation filter—A transparent body that transmits only selected wavelengths.

radiation flux density (irradiance)—The total incident radiation energy measured in power per unit area (e.g., milliwatts per square centimeter).

radiation hard—The characteristic of a material that is insensitive to nuclear or X-ray radiation.

radiation-hardened circuit—Integrated circuit manufactured with special devices and isolation techniques such that when it is exposed to heavy radiation it remains operational. Conventional circuits will short out under such conditions because the radiation generates electrical currents inside the semiconductor material.

radiation hardening—1. Manufacturing techniques applied to a device so that its performance is not degraded significantly by exposure to high gamma and neutron radiation environments. Examples are the use of dielectric isolation techniques and nichrome thin-film resistors. 2. A process of preparing components or circuits so they will be better able to withstand radiation and yet will operate. 3. A preconditioning technique used in manufacturing various electronic components. The process is employed to be sure the product's performance in the equipment is not degraded excessively by exposure to the high levels of neutron and gamma rays that are

encountered in space. The principle involved in applying this hardening to the device is to change the characteristics of the component by the preapplication of gamma or neutron rays, so as to permanently fix its electrical characteristics. Entering the hostile space environment, the preconditioned or hardened components will no longer be affected by additional gamma and neutron ray exposure.

radiation hazard—1. The health hazard caused by exposure to ionizing radiation. 2. The possible harmful effect of powerful electromagnetic radiation on the human body or on electrical components.

radiation intensity—In a given direction, the power radiated from an antenna per unit solid angle in that direction.

radiation lobe—*See* lobe.

radiation loss—In a transmission system, the portion of the transmission loss due to radiation of the radio-frequency power.

radiation monitor—A device for determining amount of exposure to radioactivity. May be periodic or continuous, may monitor an area or an individual's breath, clothing, etc.

radiation pattern—1. *See* directional pattern. 2. For a fiber or bundle, a curve of the output radiation intensity plotted against the exit angle. 3. For an optical fiber or fiber bundle, the curve of the output radiation intensity plotted as a function of the angle between the optical axis of the fiber or bundle and a normal to the surface on which the radiation intensity is being measured, i.e., the output radiation versus direction of measurement relative to the optical axis.

radiation potential—The voltage required to excite an atom or molecule and cause the emission of one of its characteristic radiation frequencies.

radiation pyrometer—Also called a radiation thermometer. 1. A pyrometer that uses the radiant power from the object or source whose temperature is being measured. Within wide- or narrow-wavelength bands filling a definite solid angle, the radiant power impinges on a suitable detector—usually a thermocouple, thermopile, or a bolometer responsive to the heating effect of the radiant power, or a photosensitive device connected to a sensitive electric instrument. 2. A temperature-measuring device that uses an optical system to focus radiant energy from an object onto a detector. The detector converts this energy into an electrical signal that varies with the temperature of the object.

radiation report—A formal report of radiation measurements made by an engineer skilled in interference control techniques. Usually required by the FCC prior to certification of industrial heating equipment.

radiation resistance—1. The power radiated by an antenna, divided by the square of the effective antenna current referred to a specified point. 2. The resistance that, if inserted in place of the antenna, would consume the

same amount of power radiated by the antenna. 3. The characteristic of a material that enables it to retain useful properties during or after exposure to nuclear radiation.

radiation sensitivity—The ratio of photoinduced current to incident radiant energy, the latter measured at the plane of the lens of a photodevice.

radiation sickness—An illness resulting from exposure to radiation.

radiation survey meter—An instrument that measures instantaneous radiation.

radiation temperature—1. The temperature to which an ideal blackbody must be heated so it will have the same emissive power as a given source of thermal radiation. 2. The temperature of a complete radiator that has a total radiant emittance identical with that of an unknown source.

radiation thermocouple—A thermocouple that is used in infrared spectroscopy to detect a sample's infrared emittance. *See* thermocouple.

radiation thermometer—*See* radiation pyrometer.

radiation transfer index—Abbreviated RTI. A parameter that describes the transmission performance of optical fiber cables. It measures cable performance and includes both coupling and propagation losses.

radiation trapping—That process whereby radiation spontaneously emitted by a volume of optical material is resonantly reabsorbed within the same volume before it escapes. This effect is manifested in a reduction in the observed rate of spontaneous emission from the material relative to the rate for single atoms or ions.

radiative equilibrium—The constant-temperature condition that exists in a material when the radiant energies absorbed and emitted are equal.

radiative recombination—In an electroluminescent diode in which electrons and holes are injected into the p-type and n-type regions by application of a forward bias, the recombining of injected minority carriers with the majority carriers in such a manner that the energy released on recombination results in the emission of photons of energy $h\nu$, which is approximately equal to the bandgap energy. Radiative recombination produces the light in a LED, which can be modulated for signaling purposes using optical fibers for transmission or integrated optical circuits for switching.

radiator—1. Any device that emits radiation. *See also* radiating element. 2. Any of the parts of an antenna that radiate electromagnetic waves, either directly into space or against a reflector.

radio—1. Communication by electromagnetic waves transmitted through space. 2. A general term, principally an adjective, applied to the use of electromagnetic waves between 10 kHz and 3000 GHz. 3. Electronic equipment for the wireless transmission or reception, or both, of electromagnetic waves, especially when used to transmit and receive sounds, activate a remote-control mechanism, etc.;

Radiation pyrometer.

a radio set. 4. The science of communicating over a distance by converting sounds or signals to electromagnetic waves and radiating these through space.

radioacoustic position finding—A method of determining distance through water. This is done by closing a circuit at the same instant a charge is exploded under water. The distance to the observing station can then be calculated from the difference in arrival times between the radio signal and the sound of the explosion.

radioacoustics—A study of the production, transmission, and reproduction of sounds carried from one place to another by radiotelephony.

radioactive—Pertaining to or exhibiting radioactivity.

radioactive isotope—*See* radioisotope.

radioactive series—A succession of radioactive elements, each derived from the disintegration of the preceding element in the series. The final element, known as the end product, is not radioactive.

radioactivity—A property exhibited by certain elements whose atomic nuclei spontaneously disintegrate and gradually transmute the original element into stable isotopes of that element or into another element with different chemical properties. The process is accompanied by the emission of alpha particles, beta particles, gamma rays, positrons, or similar radiations.

radioactivity detector—An instrument used to detect radioactive materials: alpha particles, or helium nuclei; beta particles, or free electrons; and gamma rays, which are X-rays of very short wavelength. They may be detected by their chemical effects, by ionization produced in gases at low pressure, and by their tracks formed in a cloud chamber.

radio altitude—*See* radar altitude.

radio approach aids—Equipment making use of radio to determine the position of an aircraft with considerable accuracy from the time it is in the vicinity of an airfield or carrier until it reaches a position from which a landing can be carried out.

radioastronomy—The branch of astronomy in which the radio waves emitted by certain celestial bodies are used for obtaining data about them.

radio attenuation—For one-way propagation, the ratio of the power delivered by the transmitter to the transmission line connecting it with the transmitting antenna, to the power delivered to the receiver by the transmission line connecting it with the receiving antenna.

radio beacon—Also called a radiophone or, in air operations, an aerophare. A radio transmitter, usually nondirectional, that emits identifiable signals for direction finding.

radio-beacon station—In the radionavigation service, a station whose emissions are intended to enable a mobile station to determine its bearing or direction in relation to the radio-beacon station.

radio beam—1. A radio wave in which most of the energy is confined within a relatively small angle. 2. A low-frequency radio transmitter used in direction finding for determining fixes and homing—a process of navigation whereby the pilot directs the aircraft toward the station to which it is tuned.

radio bearing—The angle between the apparent direction of a source of electromagnetic waves and a reference direction determined at a radio direction-finding station. In a true radio bearing, this reference direction is true north. Likewise, in a magnetic radio bearing, it is magnetic north.

radiobiology—The study of the effects on living matter (or substances derived therefrom) of high-energy radiation extending from X-rays to gamma rays, including

high energy beams of neutrons and charged particles, e.g., alpha particles, electrons, protons, deuterons.

radio breakthrough—The breakthrough of modulated radio signals into the channels of an audio amplifier due to the presence of high-level radio signal fields. The effect is that the base/emitter junction of the low-level input transistor rectifies the signals picked up by the wiring or circuit components, and the resulting audio is then handled by the amplifier in the ordinary way so that the radio program appears as a disconcerting background on the wanted source signal.

radio broadcast—A program of music, voice, and/or other sounds broadcast from a radio transmitter for reception by the general public.

radio broadcasting—*See* radio broadcast.

radio channel—A band of frequencies wide enough to be used for radiocommunication. The width of a channel depends on the type of transmission and on the tolerance for the frequency of emission.

radio circuit—1. A means for carrying out one radiocommunication at a time in either direction between two points. 2. A communication circuit between two points via radio. One circuit may be comprised of many channels, which may be used for teletypewriter, voice, or data communication.

radiocommunication—An overall term for transmission by radio of writing, signs, signals, pictures, and sounds of all kinds.

radiocommunication circuit—A radio system for carrying out one communication at a time in either direction between two points.

radiocommunication guard—A communication station designated to listen for and record transmission and to handle traffic on a designated frequency for a certain unit or units.

radio compass—*See* direction finder.

radio control—Remote control of apparatus by radio waves (e.g., model airplanes, boats).

radio deception—Sending false dispatches, using deceptive headings or enemy call signs, etc., by radio to deceive the enemy.

radio detection—Also called radio warning. Determining the presence of an object by radiolocation, but not its precise position.

radio detection and location—Use of an electronic system to detect, locate, and predict future positions of an earth satellite.

radio detection and ranging—Abbreviated radar. 1. Any of certain methods or systems of using beamed and reflected electromagnetic energy for detecting and locating objects; for measuring distance, velocity, or altitude; or for other purposes such as navigating, homing, bombing, missile tracking, mapping, etc. 2. In Federal Communications Commission regulations, a radiodetermination system based on the comparison of reference signals with radio signals reflected or retransmitted from the position to be determined. *See also* radar.

radio direction finder—A radio receiver that pinpoints the line of travel of the received waves.

radio direction finding—Abbreviated RDF. Radiolocation in which only the direction, not the precise location, of a source of radio emission is determined by means of a directive receiving antenna.

radio direction-finding station—A radiolocation station that determines only the direction of other stations, not their location, by monitoring their transmission.

radio Doppler—A device for determining the radial component of the relative velocity of objects by observing the frequency change due to such velocity.

radioelectrocardiogram—A broadcast electrocardiogram signal from the subject to a remote receiver. It

makes an ECG practical while the subject is exercising or during natural work or home activities.

radioelectroencephalograph—An electroencephalograph in which a radio link is used so that the patient may move about while the electroencephalogram is being recorded.

radio engineering—The branch of engineering concerned with the generation, transmission, and reception of radio (and television) waves, and with the design, manufacture, and testing of associated equipment.

radio fadeout—Also called the Dellinger effect. The partial or complete absorption of substantially all radio waves normally reflected by the ionospheric layers in or above the E region.

radio field intensity—Also called radio field strength. The maximum (unless otherwise stated) electric or magnetic field intensity at a given location associated with the passage of radio waves. It is commonly expressed as the electric field intensity in microvolts, millivolts, or volts per meter. For a sinusoidal wave, its root-mean-square value is commonly stated instead.

radio field strength—*See* radio field intensity.

radio field-to-noise ratio—The ratio of the field intensity of the desired wave to the noise field intensity at a given location.

radio fix—1. A method by which the position source of radio signals can be determined. Two or more radio direction finders monitor the transmission and obtain cross bearings. The position can then be pinpointed by triangulation. 2. The method by which a ship, aircraft, etc., equipped with direction finding equipment can determine its own position. This it does by obtaining radio bearings from two or more transmitting stations of known location. The position can then be pinpointed by triangulation as in (1) above.

radio-fixing aids—Equipment making use of radio to assist a user in determining his or her geographical position.

radio frequency—Abbreviated rf. 1. Any frequency at which coherent electromagnetic radiation of energy is possible. 2. A term describing incoming radio signals to a receiver or outgoing signals from a radio transmitter. There are no finite limits in the rf range, but it is usually considered to denote frequency above 150 kHz and extending up to the infrared range.

radio-frequency alternator—A rotating generator that produces radio-frequency power.

radio-frequency amplification—Amplification of a signal by a receiver before reflection, or by a transmitter before radiation.

radio-frequency choke—An inductor used to impede the flow of radio-frequency currents. Its core is generally air or pulverized iron.

radio-frequency component—In a signal or wave, the portion consisting of the rf alternations only—not its audio rate of change in amplitude or frequency.

radio-frequency converter—A power source for producing electrical power at frequencies of 10 kHz and above.

radio-frequency generator—In industrial and dielectric heaters, a power source comprising an electron-tube oscillator, an amplifier (if used), a power supply, and associated control equipment.

radio-frequency heating—1. The process of heating a substance by subjecting it to a high-frequency energy field. *See also* dielectric heating. 2. A heating and drying process utilizing radio-frequency energy to generate heat in a dielectric material (nonmetallic) by molecular friction.

radio-frequency interference—Abbreviated RFI. Any electrical signal capable of being propagated into and interfering with the proper operation of electrical or electronic equipment. The frequency range of such interference may be taken to include the entire electromagnetic spectrum.

radio-frequency motion detector—A sensor that detects the motion of an intruder through the use of a radiated radio-frequency electromagnetic field. The device operates by sensing a disturbance in the generated rf field caused by intruder motion, typically a modulation of the field referred to as a Doppler effect, which is used to initiate an alarm signal. Most radio-frequency motion detectors are certified by the FCC for operation as “field disturbance sensors” at one of the following frequencies: 0.915 GHz (L-band), 2.45 GHz (S-band), 5.8 GHz (X-band), 10.525 GHz (X-band), or 22.125 GHz (K-band). Units operating in the microwave frequency range are usually called microwave motion detectors.

radio-frequency oscillator—An oscillator that generates alternating current at radio frequencies.

radio-frequency pacemaker—A pacemaker that consists of an implanted circuit designed to receive pacing signals from an extracorporeal transmitter.

radio-frequency preheating—A method of preheating used in the molding of materials so that the molding operation may be facilitated or the molding cycle reduced. The frequencies used most often are between 10 and 100 MHz.

radio-frequency pulse—A radio-frequency carrier that is amplitude modulated by a pulse. Between pulses, the modulated carrier has zero amplitude. (The coherence of the carrier with itself is not implied.)

radio-frequency resistance—*See* skin effect.

radio-frequency signal generator—*See* rf signal generator.

radio-frequency suppressor—A device that absorbs radiated energy that might interfere with radio reception.

radio-frequency transformer—A transformer used with radio-frequency currents.

radio-frequency welding—Also called high-frequency welding. A method of welding thermoplastics using a radio-frequency field to apply the necessary heat.

radiogoniometer—In a radio direction finder, the part that determines the phase difference between the two received signals. The Bellini-Tose system has two loop antennas, both at right angles to each other and connected to two field coils in the radiogoniometer. Bearings are obtained by rotating a search coil inductively coupled to the field coils.

radiogram—A message sent via radio telegraphy.

radiograph—1. An X-ray film image that shows internal structural features of the body. 2. An X-ray or radium photograph illustrating the nonuniformity or density of the structure the rays penetrate. *See* radiophoto.

radiography—Any nondestructive method of internal examination in which metal objects are exposed to a beam of X-ray or gamma radiation. Differences in thickness, density, or absorption caused by internal defects or inclusions are apparent in the shadow image, either on a fluorescent screen or on photographic film placed behind the object.

radio guard—A ship, aircraft, or radio station designated to listen for and record transmissions and to handle traffic on a designated frequency for a certain unit or units.

radio guidance system—A system that makes use of radio signals in guiding a missile or vehicle in flight. The system includes both the flightborne equipment and the guidance-station equipment on the ground.

radio homing aids—Radio equipment used to assist in the location of an area with sufficient accuracy that an approach may be effected.

radio horizon—The boundary line beyond which direct rays of the radio waves cannot be propagated over the earth's surface. This distance is not a constant; rather, it is affected by atmospheric refraction of the waves.

radio inertial-guidance system—A command type of guidance system consisting essentially of the following: (a) A radar tracking unit, comprising radar equipment on the ground, one or more transponders in the missile, and necessary communications links to the guidance station. (b) A computer that accepts missile position and velocity information from the tracking system and furnishes appropriate signals to the command link to steer the missile. (c) The command link, which consists of a transmitter on the ground and an antenna and receiver on the missile; actually, the command link is built into the tracking unit. (d) An inertial system for partial guidance in case of radio guidance failure.

radio influence—Radio-frequency interference that originates on and from power lines.

radio intelligence—Interception and interpretation of enemy radio transmissions.

radio intercept—1. An act or instance of interception of a radio message. 2. An intercepted radio message. 3. A service or agency that intercepts radio messages.

radio interference—Undesired conducted or radiated electrical disturbances, including transients, which can interfere with the operation of electrical or electronic equipment. These disturbances fall between 14 kHz and 10 GHz.

radioisotope—Also called radioactive isotope. 1. The isotope produced when an element is placed into a nuclear reactor and bombarded with neutrons. Radioisotopes are used as tracers in many areas of science and industry. Like all isotopes, they decay spontaneously with the emission of their radiation at a definite rate measured by their half-lives. 2. Tracer form of an element having similar chemical behavior but "tagged" with a radioactive substance (chromium, iodine, phosphor, etc.) so that it emits gamma rays that can be counted with a scintillation counter.

radio jamming—Blocking communications by sending overpowering interference signals.

radio knife—A form of surgical knife that uses a high-frequency electric arc at its tip to cut tissue and, at the same time, also sterilizes the edges of the wound.

radio landing aids—Radio equipment used in assisting an aircraft in making its actual landing.

radio landing beam—A distribution of vertical directional radio waves used for guiding aircraft into a landing.

radio link—A radio system used to provide communication between two specific points.

radiolocation—1. Use of the constant-velocity or rectilinear propagation characteristics of radio waves to detect an object or to determine its direction, position, or motion. 2. With respect to Federal Communications Commission regulations, radiodetermination used for purposes other than those of radionavigation.

radiolocation service—A radio service in which radiolocation is used.

radiolocation station—A radio station in the radiolocation service.

radio log—A record of all messages sent and received, transmitter tests made, and other important information pertaining to the operation of a particular station.

radiologist—A specialist in the field of radiology.

radiology—The branch of medical science that deals with the use of radiant energy in the diagnosis and treatment of disease. While radiology originally involved only the use of radiant energy in visualizing tissues, this science now covers a wide spectrum of diagnostic and therapeutic applications, such as diagnosis using roentgen rays, diagnosis using radioisotope scanning techniques, genetic radioisotopes in research, roentgen cinematography, angiography, spectroscopy, and treatment of tumors using roentgen rays, implanted radioactive pellets, cyclotrons, or lasers.

radioluminescence—Luminescence produced by radiant energy (e.g., by X-rays, radioactive emissions, alpha particles, or electrons).

radiomagnetic indicator—Abbreviated RMI. A navigational instrument used by land vehicles. It presents a display combining the heading and the relative and magnetic bearings of the vehicle with the relative bearing of a radio station whose location is known.

radio marker beacon—In the aeronautical radionavigation service, a land station that provides a signal to designate a small area above the station.

radio marker station—Station marking a definite location on the ground as an aid to air navigation.

radiometallography—X-ray examination of the crystalline structure and other characteristics of metals and alloys.

radiometeorograph—A meteorograph which, when carried into the stratosphere by an unmanned gas-filled rubber balloon, automatically reports atmospheric conditions by radio as it ascends into the stratosphere. The ultrahigh-frequency signals are transmitted so that they can be recorded and interpreted in terms of pressure, temperature, and humidity. *See also* radiosonde.

radiometer—1. A device for measuring radiant flux density. Generally, a blackened thermocouple or bolometer is employed, but the simplest type employs a rotating vane. 2. An instrument for measuring intensity of radiant energy, including X-ray. A Nicols or Crookes radiometer detects the energy by the torsional twist of suspended

Radiometer.

vanes that are blackened on one side and exposed to radiant energy.

radiometric — Pertaining to the measurement of radiation.

radiometry — 1. The measurement of the spectral emission characteristics of sources of electromagnetic radiation. 2. The science of radiation measurement concerned with the detection and measurement of radiant energy either at separate wavelengths or integrated over a broad wavelength band, and the interaction of radiation with matter, such as absorption, reflectance, and emission. 3. The measurement of radiation in the infrared, visible, and ultraviolet portion of the spectrum.

radiomicrometer — *See* microradiometer.

radionavigation — Navigational use of radiolocation for determining position or direction, or for providing a warning of obstructions. Radionavigation includes use of radio direction finding, radio ranges, radio compasses, radio homing beacons, etc.

radionavigation land station — A fixed station in the radionavigation service—i.e., one not intended for mobile operation.

radionavigation mobile station — A radionavigation station operated from a vehicle.

radionavigation service — A radiolocation service used for radionavigation.

radio net — A system of radio stations that communicate with each other. A military net usually is made up of a radio station of a superior unit and stations of all subordinate or supporting units.

radio-noise field intensity — A measure of the field intensity of interfering electromagnetic waves at some point (e.g., a radio receiving station). In practice, the field intensity itself is not measured, but some proportionate quantity.

radiopaque — Not penetrable by X-rays or other radiation. (The opposite of radioparent.)

radioparent — Penetrable by X-rays or other radiation. (The opposite of radiopaque.)

radiophone — *See* radio beacon; radiotelephone.

radiophoto — Also called radiophotography, radiophotograph, radiophotogram, facsimile, or radiograph. The transmission of photographs and other illustrations by radio.

radiophotogram — *See* radiophoto.

radiophotograph — A photograph transmitted by radio waves.

radiophotography — The transmission of photographic images or pictures by radio waves.

radiophotoluminescence — The property whereby the previous exposure of certain materials to nuclear radiation enables them to give off visible light when irradiated with ultraviolet light.

radio position finding — Determining the location of a radio station by using two or more direction finders and a process of triangulation.

radiopositioning land station — A station, other than a radionavigation station, in the radiolocation service not intended to be operated while in motion.

radiopositioning mobile station — A station, other than a radionavigation station, in the radiolocation service intended to be operated while in motion or while stopped at unspecified points.

radio prospecting — The use of radio equipment to locate mineral or oil deposits.

radio proximity fuse — A radio device that detonates a missile by electromagnetic interaction within a predetermined distance from the target.

radio pulse — An intense, split-second burst of electromagnetic energy.

radio range — A radionavigational facility whose emissions provide radial lines of position by having special characteristics that are recognizable as bearing information and useful in lateral guidance of aircraft.

radio range beacon — A radionavigation land station in the aeronautical radionavigation service providing radio equisignal zones.

radio range finding — Determination of range by means of radio waves.

radio range leg — The space within which an aircraft will receive an on-course signal from a radio range station.

radio range monitor — An instrument that automatically monitors the signal from a radio range beacon and warns attending personnel when the transmitter deviates from its specified current bearings. It also transmits a distinctive warning to approaching planes whenever trouble exists at the beacon.

radio range station — A land station that operates in the aeronautical radionavigation service and provides radial equisignal zones.

radio receiver — A device for converting radio waves into signals perceptible to humans.

radio reception — Reception of radioed messages, programs, or other intelligence.

radio recognition — The use of radio means to determine the friendly or hostile character or the individuality of another.

radio relay — *See* radio-relay system.

radio-relay system — Also called radio relay. A radio transmission system in which the signals are received and retransmitted from point to point by intermediate radio stations.

radio set — A radio transmitter, radio receiver, or a combination of the two.

radio shielding — A metallic covering over all electric wiring and ignition apparatus that is grounded at frequent intervals for the purpose of eliminating electric interference with radiocommunications.

radio signal — A signal that is transmitted by a radio.

radio silence — A period during which all or certain radio equipment capable of radiation is kept inoperative.

radiosonde — A balloonborne instrument for the simultaneous measurement and transmission of meteorological data. The instrument consists of transducers for the measurement of pressure, temperature, and humidity; a modulator for conversion of the output of the transducers to a quantity that controls a property of the radio-frequency signal; a selector switch that determines the sequence in which the parameters are to be transmitted; and a transmitter that generates the radio-frequency carrier.

Radiosonde system.

Radio spectrum

Band number	Frequency range*	Metric subdivision	Band designation
4	3–30 kHz	Myriametric waves	VLF
5	30–300 kHz	Kilometric waves	LF
6	300–3000 kHz	Hectometric waves	MF
7	3–30 MHz	Decametric waves	HF
8	30–300 MHz	Metric waves	VHF
9	300–3000 MHz	Decimetric waves	UHF
10	3–30 GHz	Centimetric waves	SHF
11	30–300 GHz	Millimetric waves	EHF
12	300–3000 GHz or 3 THz	Decimillimetric waves	—

*Lower limit is exclusive, upper limit inclusive.

radiosonde recorder—An instrument that is located at the surface observing station and is used to record the data presented by a radiosonde aloft. The mechanism of the recorder depends upon the type of radiosonde system used.

radiosonde transmitter—The component of the radiosonde that includes the modulating blocking oscillator and the radio-frequency carrier oscillator.

radiosonobuoy—See sonobuoy.

radio spectrum—The range of frequencies of electromagnetic radiation usable for radiocommunication. The radio spectrum may range from 3 kHz to over 300 GHz. Corresponding wavelengths are 100 km to 1 mm.

radio station—An assemblage of equipment for radio transmission, reception, or both.

radio-station interference—Interference caused by reception of radio waves from other than the desired station.

Radio Technical Commission for Aeronautics—A cooperative, nonprofit association of all telecommunications agencies of the U.S. government and industry. Its purpose is to advance the art and science of aeronautics through investigation of all available or potential applications of the telecommunications art, coordination of these applications with allied arts, and the adaptation of them to recognized operational requirements.

radiotelegraph transmitter—A radio transmitter capable of handling code signals.

radiotelegraphy—Radiocommunication by means of the International Morse code or some other, similarly coded, signal.

radiotelephone—Also called radiophone. The complete radio transmitter, receiver, and associated equipment required at one station for radiotelephony.

radiotelephone distress signal—The spoken word MAYDAY (phonetic spelling of the French expression *m'aidez*, or "help me"). It corresponds to SOS in radiotelegraphy and is used by aircraft, ships, etc., needing help.

radiotelephone transmitter—A radio transmitter capable of handling audio-frequency modulation (e.g., voice and music).

radiotelephony—Two-way transmission and reception of sounds by radio.

radio telescope—1. A very sensitive radio receiver that is used in conjunction with a large and highly directional antenna to receive signals from an object or region in space. 2. An instrument designed to collect naturally formed extraterrestrial electromagnetic radiation

within the radio-frequency range of the spectrum in amounts sufficient to be measured.

radioteletype—See RTTY.

radiotherapy—The treatment of disease with radiation, especially ultraviolet, infrared, X-rays, and gamma rays.

radiothermics—The application of heat generated by radio waves (e.g., in diathermy or electronic heating).

radio transmission—Transmission of signals by electromagnetic waves other than light or heat waves.

radio transmitter—A device capable of producing radio-frequency power and used for radio transmission.

radiotransparent—Permitting the passage of X-rays or similar radiation.

radio tube—A general term for any type of electron tube used in electronic equipment.

radiovision—An early name for television.

radio warning—See radio detection.

radio watch—Also called watch. The vigil maintained by an operator when on duty in the radio room of a vessel and listening for signals—especially on the international distress frequencies.

radio wave—1. Electromagnetic wave at a frequency lower than 3000 GHz and propagated through space without an artificial guide. 2. Combination of electric and magnetic fields varying at a radio-frequency rate and capable of travelling through space at the speed of light. It is produced by feeding the output of a radio transmitter into a transmitting antenna.

radio wavefront distortion—A change in the direction of advance of a radio wave.

radio-wave propagation—The transfer of energy by electromagnetic radiation at frequencies below approximately 3×10^{12} hertz.

radist—The radionavigation system in which the position of a vehicle is determined by comparing the arrival times of transmitted pulses at three or more ground stations.

radix—Also called the base. 1. The total number of distinct marks or symbols used in a numbering system. For example, since the decimal numbering system uses ten symbols (0, 1, 2, 3, 4, 5, 6, 7, 8, 9), the radix is 10. In the binary numbering system the radix is 2, because there are only two marks or symbols (0, 1). 2. In positional representation, that integer, if it exists, by which the significance of the digit place must be multiplied to give the significance of the next higher digit place. For example, in decimal notation, the radix of each place is 10. 3. Total number of characters available to each position of a digital numeric system.

radix complement—Also called true complement. A number obtained by subtracting each digit of the given number from one less than the radix, then adding to the least significant digit, executing all required carries. Examples are the tens complement in decimal notation and the twos complement in binary notation.

radix-minus-one complement—Also called diminished-radix complement. A number obtained by subtracting each digit of the given number from one less than the radix. Examples are the nines complement in decimal notation and the ones complement in binary notation.

radix notation—A positional representation in which any two adjacent digit positions have significances in an integral ratio called the radix of the least significant of the two positions; the digit in any position may have a value from zero to one less than the radix of that position.

radix point—Also called base point, and binary point, decimal point, etc., depending on the numbering system. The index that separates the integral and fractional digits of the numbering system in which the quantity is represented.

radome—Also called radar dome. The housing that protects a radar antenna from the elements, but does not block radio frequencies.

radux—A long-distance, low-frequency navigational system that provides hyperbolic lines of position. It is of the continuous-wave, phase-comparison type.

railing—Radar pulse jamming at high recurrence rates (50 to 150 kHz). On a radar indicator, it results in an image resembling fence railing.

railings—The pattern produced on an A-scope by continuous waves modulated with a high-frequency signal. It appears as a series of vertical lines resembling target echoes along the baseline.

rain-barrel effect—The characteristic sound noted on an equalized line that is overcompensated.

rainbow—The technique that applies pulse-to-pulse frequency changing to identify and discriminate against decoys and chaff.

rainbow generator—A signal generator with which the entire color spectrum can be produced on the screen of a color television receiver. The colors merge together as in a rainbow. *See also* keyed rainbow generator.

rake angle—The angle that a stylus makes with a phonograph record when viewed from the side.

RAM—Abbreviation for random-access memory.

ram—The moving part of the head of a crimping tool.

ramark—Also called a radar marker. A fixed radar transmitter that emits a continuous signal that is used as a bearing indication on a radar display.

ramp—A voltage or current that varies at a constant rate; for example, that portion of the output waveform of a time/linear sweep generator used as a time base for scope display.

ramping—Control method used to vary the pulse rate from one value to another, to produce either acceleration or deceleration of a stepper motor.

ramp input—A change, in an input signal, that varies at a constant rate.

Ramsauer effect—The absorption of slow-moving electrons by intervening matter.

random—Irregular; having no set pattern.

random access—1. Access to a computer storage under conditions whereby there is no rule for predetermining the position from where the next item of information is to be obtained 2. The process of obtaining information from the computer storage with the access time independent of the location of the information. 3. Access method in a computer in which each word can be retrieved directly

by its address. 4. The ability to gain access to any location of a memory unit in a time that is independent of the location itself. 5. A term used to describe computer files that do not have to be searched sequentially to find a particular record but can be addressed directly. 6. The ability of a computer to directly access random bits of memory without going through a predefined sequence of locations.

random-access device—Also called direct-access device. A data-storage device in which the access time is effectively independent of the location of the stored data.

random-access memory—Abbreviated RAM. 1. A storage arrangement from which information can be retrieved with a speed that is independent of the location of the information in the storage. For example, a core memory is a random-access memory, but a magnetic tape memory is not. 2. A device that permits individual interrogation of any memory cell in a completely random sequence. Any point in the total memory system can be accessed without looking at any other bit. 3. A memory that may be written to, or read from, any address location in any order. May refer specifically to the integrated circuit method of implementation. 4. A read/write memory, usually a permanent memory, that stores information in such a way that each bit of information may be retrieved within the same amount of time as any other bit. As opposed to serial memory. 5. A type of memory that offers access to storage location within it by means of X and Y coordinates. 6. The main memory of a computer. Instructions can be written into and read out of RAM, and its contents can be changed at any time. But its contents are wiped clean when power is shut off. *See* ROM. 7. A type of memory that is used to store and retrieve digital data that is constantly being changed, updated, or modified in some way. 8. A memory in which the central processor can access all locations with equal facility. Sometimes called read/write memory because data can be added to or removed from such memory as an ordinary procedure. RAM is used for both storage of a computer operation program and for data. 9. A memory that permits access to any of its address locations in any desired sequence with similar access time to each location. The term has come to mean only a read/write memory, not a ROM or EPROM, which, strictly speaking, are also random-access memories.

random-access programming—Programming a problem for a computer without regard to the access time to the information in the registers called for in the program.

random-access storage—A form of storage in which information can be recovered immediately, regardless of where it was stored. For example, magnetic-core memory devices will usually yield any bit of information with almost no time penalty regardless of where it is located, while magnetic tape must be run until the required information can be found.

random bundle—A fiber-optics bundle that scrambles an image but can convey light from a source to a relatively inaccessible point, and then again from that location to a photocell.

random error—The inherent imprecision of a given process of measurement; the unpredictable component of repeated independent measurements on the same object under sensible uniform conditions, usually of an approximately normal (Gaussian) frequency distribution, other than systematic or erratic errors and mistakes, sometimes called short-period errors.

random experiment—An experiment that can be repeated a large number of times but may yield different results each time, even when performed under similar circumstances.

random failure—Also called chance failure. 1. Any chance failure whose occurrence at a given time is unpredictable. 2. Any failure whose cause and/or mechanism make its time of occurrence unpredictable, but which is predictable only in a probabilistic or statistical sense.

random-function generator—A device that generates nonrepetitive signals that are distributed over a broad frequency range.

random-impulse generator—A generator of electrical impulses that occur at random rather than at specific intervals.

random interlace—A technique for scanning in which there is no fixed relationship between adjacent lines in successive field; often used in closed-circuit television systems. It offers somewhat reduced precision to that employed in commercial broadcast service.

randomized jitter—Jitter produced by means of noise modulation.

random logic—A collection of various gates interconnected to perform a variety of functions. Random-logic circuits form no repetitive pattern and are more difficult to fabricate by conventional LSI/CMOS techniques than is repetitive logic. However, new high-density CMOS fabricating techniques overcome the old restrictions and allow large-scale integration of random logic.

randomness—1. A condition of equal chance for the occurrence of any of the possible outcomes. 2. The occurrence of an event in accordance with the laws of chance.

random noise—Also called fluctuation noise. 1. A signal whose instantaneous amplitude is determined at random and therefore is unpredictable. It contains no periodic frequency components and its spectrum is continuous. *See also* broadband electrical noise. 2. Noise generated in a circuit by random movement of electrons caused by thermal agitation. In tape recording it can be caused by uneven distribution of magnetized particles and is reproduced as a background hiss. 3. Transient perturbations occurring at random with a Gaussian spectral distribution equivalent to thermal noise. Thermal and shot noise are forms of random noise that may be present in all portions of a telecommunications system, being more significant, of course, at points of lower signal-to-noise ratio. 4. Essentially, noise that cannot be predicted. Therefore, even if the magnitude of sound or oscillation in a system is known at a given moment, random noise can change in a short time. 5. Noise composed of many uncoordinated and overlapping transient disturbances occurring at random.

random-noise generator—A generator of a succession of random signals that are distributed over a wide frequency spectrum.

random-number generator—A special machine routine or hardware that produces a random number or series of random numbers in accordance with specified limitations.

random numbers—1. A set of digits such that each successive digit is equally likely to be any of n digits to the base n of the number. 2. Numbers composed of digits selected from an orderless sequence of digits. 3. Array of independent digits having no logical interrelationship, so that the occurrence of any particular one is totally unpredictable. 4. A sequence of integers or group of numbers (often in the form of a table) that show absolutely no relationship to each other anywhere in the sequence. At any point, all integers have an equal chance of occurring, and they occur in an unpredictable fashion.

random PARD—Pertains to that portion of the total PARD in an electric power supply that is not periodic. This phenomenon is frequently referred to as noise.

random processing—The treatment of information without respect to where it is located in external storage and in an arbitrary sequence determined by the input against which it is to be processed.

random pulsing—Varying the repetition rate of pulses by noise modulation or continuous frequency change.

random sample—A sample in which every item in the lot is equally likely to be selected in the sample.

random sampling—1. A sampling process in which there is a significant time uncertainty between the signal being sampled and the taking of samples. 2. A selection of observations taken from all of the observations of a phenomenon in such a way that each chosen observation has the same possibility of selection.

random-sampling oscilloscope—An oscilloscope that functions by constructing a coherent display from samples taken at random.

random sequential memory—A memory in which one reference can be found immediately; the other reference is found in a fixed sequence.

random signals—Waveforms having at least one parameter (usually amplitude) that is a random function of time (e.g., thermal noise or shot noise).

random variable—Also called variate or stochastic variable. 1. The result of a random experiment. 2. A discrete or continuous variable that may assume any one of a number of values, each having the same probability of occurrence. 3. Any signal whose amplitude or phase cannot be predicted by a study of previous values of the signal.

random variation—A fluctuation in data that is due to uncertain or random occurrences.

random velocity—The instantaneous velocity of a particle without regard to direction. It may be characterized by its distribution function or by its average, root-mean-square, or most probable value.

random vibration—A vibration generally composed of a broad, continuous spectrum of frequencies, the instantaneous magnitude of which cannot be specified to any given moment of time. Instantaneous amplitude can only be defined statistically by a probability distribution function that gives the fraction of the total time that the amplitude lies within specified amplitude intervals. (If random vibration has instantaneous magnitudes distributed according to the Gaussian distribution, it is called Gaussian random vibration.) *See also* white noise.

random winding—A coil winding in which the turns and layers are not regularly positioned or spaced but are positioned haphazardly.

random wound—Describing a coil wound without care to ensure that the wire is in layers. Random-wound coils have fewer turns for a given volume.

range—1. The maximum useful distance of a radar or radio transmitter. 2. The difference between the maximum and the minimum value of a variable. 3. The set of values that may be assumed by a quantity or function. 4. *See* receiving margin.

range-amplitude display—A radar display in which a time base provides the range scale from which echoes appear as deflections normal to the base.

range calibration—Adjustment of radar-range indications by use of known range targets or delayed signals so that, when on target, the radar set will indicate the correct range.

range coding—A method of coding a beacon response so that the response appears as a series of pulses on a radarscope. The coding provides identification.

range finder—1. A movable, calibrated unit of the receiving mechanism of a teletypewriter that can be used

to move the selecting interval relative to the start signal. 2. An optical distance finder that depends on triangulation of two convergent beams on an object from disparate viewpoints. A pair of unaided human eyes coupled with a computerlike brain can estimate distance, at least for nearby objects, with some accuracy. 3. A device that depends on the measurement of time of wave travel from an object to a point, as in radar and sonar.

range gate—A gate voltage used to select radar echoes from a very short range interval.

range-height indicator—Abbreviated RHI. A radar display on which an echo appears as a bright spot on a rectangular field. The slant range is indicated along the *x*-axis, and the height above the horizontal plane (on a magnified scale) along the *y*-axis. A cursor shows the height above the earth.

range mark—*See* distance mark.

range marker—A variable or movable discontinuity in the range time base of a radar display (in the case of a PPI, a ring). It is used for measuring the range of an echo or calibrating the range scale.

range of an instrument—*See* total range of an instrument.

range of gain—The minimum and maximum gain to which the amplifier can be set.

range resolution—The minimum difference in range between two radar targets along the same line of bearing for which an operator can distinguish between targets.

range ring—An accurate, adjustable ranging mark on a plan-position indicator corresponding to a range step on a type-M indicator.

range step—The vertical displacement on an M-indicator sweep to measure range.

range surveillance—Surveillance of a missile range by means of electronic and other equipment.

range unit—A radar-system component used for control and indication (usually counters) of range measurements.

range zero—Alignment of the start of a sweep trace with zero range.

ranging oscillator—An oscillator circuit containing an LC resonant combination in the cathode circuit, usually used in radar equipment to provide range marks.

rank—To arrange in a series in ascending or descending order of importance.

rapid memory—*See* rapid storage.

rapid storage—Also called rapid memory, fast-access storage, and high-speed storage. Computer storage in which the access time is very short; rapid access usually is gained by limiting the storage capacity.

rare gas—*See* noble gas.

raser—Acronym for radio amplification by stimulated emission of radiation, a chemical pumping process that is accomplished without external radiation.

raster—1. On the screen of a cathode-ray tube, a predetermined pattern of scanning lines that provide substantially uniform coverage of an area. 2. The illuminated area produced by the scanning lines on a television picture tube when no signal is being received. 3. Rectangular line pattern of light produced on the screen of a cathode-ray tube with no signal present. It is formed by deflecting the electron beam rapidly from left to right and relatively slowly from top to bottom. 4. The pattern of lines traced by rectilinear scanning in display systems. 5. The visible part of the picture displayed by a monitor or TV set.

raster burn—In camera tubes, a change in the characteristics of the area that has been scanned. As a result, a spurious signal corresponding to that area will be produced when a larger or tilted raster is scanned.

raster display—1. A display in which the entire display surface is scanned at a constant refresh rate. 2. A refresh graphics system in which the electron beam sweeps horizontally across the face of the CRT from left to right, drawing the picture as a series of scan lines. At the end of each line, the beam is turned off and repositioned down and to the left (the horizontal retrace) for the start of the next line. After the last line has been drawn, the beam is repositioned at the upper left corner (the vertical retrace) and the scan is repeated. Interlaced displays require two such scans to complete each picture; the first scan draws the odd-numbered lines, and the second scan draws the even-numbered lines. Horizontal vectors tend to flicker at 30 Hz on interlaced displays since they fall on a single scan line. Noninterlaced displays draw the entire picture every scan. The display scan rate always matches the ac line frequency, resulting in a 60-Hz refresh rate for noninterlaced displays and 30-Hz for interlaced.

raster scan—1. The most basic method of sweeping a CRT one line at a time to generate and display images. This method is used in commercial television in the United States. 2. Line-by-line sweep across the entire display surface to generate elements of a display image.

raster scanning—1. Radar antenna scanning similar to electron-beam scanning in a television picture tube; a horizontal sector scan that is changed in elevation. 2. A process whereby displays are generated through repetitive video scan lines. For best appearance, 10 raster scans per 5 × 7 character and 12 scans per 7 × 9 character are required with underlined cursors.

raster-scan technology—A technique similar to that used in consumer color TVs, whereby an electron beam scans across and down the screen, turning on and off at selected points or addresses. Because the screen of a color CRT uses three phosphor colors, it provides an unlimited palette of colors and gray-scale values.

ratchetjaw—CB radio term for one who often talks on radio.

ratchet relay—A stepping relay actuated by an armature-driven ratchet.

rate action—Also called derivative action. Corrective action whose rate is determined by how fast the error being corrected is increasing.

rate center—A specified geographic location used by telephone companies to determine mileage measurements for the application of interexchange mileage rates.

rated capacitance—The capacitance value for which a capacitor has been designed; usually indicated on the capacitor.

rated contact current—The current that contacts are designed to handle for their rated life.

rated current (for ac capacitors)—The rms value of the alternating current at rated frequency and rated temperature for which the capacitor is designed.

rated operational voltage—The voltage on which a specific application rating of a device is based.

rated output—1. The output power, voltage, current, etc., at which a machine, device, or apparatus is designed to operate under normal conditions. 2. The power, voltage, or current that a device (or machine) can put out for long periods without becoming overheated under specified conditions of ambient temperature and ventilation.

rated power output—Also called continuous power output or rms power output. 1. The normal radio-frequency power-output capability (peak or average) of a transmitter under optimum adjustment and operation conditions. 2. The maximum power that an amplifier will deliver continuously without exceeding its specified distortion rating.

rated range—The nominal range within which a device can be operated and still maintain the level of performance specified for it by the manufacturer.

rated ripple current—The maximum rms alternating current of specified frequency that may be applied continuously to a capacitor at a specified temperature. This is a specific term used for electrolytic capacitors.

rated ripple voltage—The rms value of the maximum alternating voltage of a specified frequency superimposed on the direct voltage that may be applied continuously to a capacitor at a specified temperature.

rated-safe plate dissipation—The number of watts that can be used to heat the plate of a vacuum tube without damaging the tube.

rated temperature—The maximum temperature at which an electric component can operate for extended periods without loss of its basic properties.

rated thermal current—In a contactor, that current at which the permissible temperature rise is reached.

rated voltage—1. The voltage at which a device or component is designed to operate under normal conditions. 2. The maximum voltage at which an electric component can operate for extended periods without undue degradation or safety hazard.

rate effect—The anode-voltage transients that cause pnpn devices to switch into high conduction.

rate generator—A proportional element that converts angular speed into a constant-frequency output voltage. *See also* angular velocity.

rate-grown junction—A grown junction, in a semiconductor, produced by varying the rate of crystal growth periodically so that n-type impurities alternately predominate.

rate-grown transistor—Also called graded-junction transistor. A variation of the double-doped transistor, in which n- and p-type impurities are added to the melt.

rate gyro—A particular kind of gyroscope used for measuring angular rates. A system of three rate gyros, each oriented to one of three mutually perpendicular axes—roll, pitch, and yaw—can control a missile or aircraft by detecting angular rates and then generating proportional corrective signals.

Rate gyro.

rate limit—*See* slew rate, 2.

rate limiting—Nonlinear behavior in an amplifier due to its limited ability to produce large, rapid changes in output voltage (slewing), restricting it to rates of change of voltage lower than might be predicted by observing the small signal frequency response.

ratemeter—1. An instrument for measuring the rates at which counts are received, usually in counts per minute. 2. A type of radiation detector whose output is proportional to instantaneous radiation intensity (rate of radioactivity emission).

rate of decay—The rate at which the sound-pressure level (velocity level, or sound-energy density level) is decreasing at a given point and at a given time. The practical unit is the decibel per second.

rate-of-rise relay—*See* instantaneous overcurrent relay.

rate-of-rise timer—A percentage timer as applied in a temperature control system for controlling the rate of temperature rise. Usually a standard percentage timer with a dial marked in various scales of degrees per hour rise.

rate of transmission—*See* speed of transmission.

rate receiver—A device for receiving a signal giving the rate of speed of a launched missile.

rate signal—A signal proportional to the time derivative of a specified variable.

rate test—A test to verify that the time constants of the integrators in an analog computer are correct.

rate transmitter—A guidance antenna used to signal the desired speed for a missile in flight.

rating—A value that establishes either a limiting capability or a limiting condition for an electronic device. It is determined for specified values of environment and operation, and may be stated in any suitable terms. (Limiting conditions may be either maxima or minima.)

rating system—The set of principles on which electronic device ratings are established and which determines their interpretation. (The rating system indicates the division of responsibility between the device manufacturer and the circuit designer, with the object of ensuring that the working conditions do not exceed the ratings.)

ratio—The value obtained by dividing one number by another. This value indicates their relationship to each other.

ratio arms—Two adjacent arms of a Wheatstone bridge, both having an adjustable resistance and so arranged that they can be set to have any of several fixed ratios to each other.

ratio calibration—1. The calibration of a dimensionless quantity that represents the ratio of one of its values to another. 2. A method by which potentiometric transducers may be calibrated, in which the value of the measurand is expressed in terms of decimal fractions representing the ratio of output resistance to total resistance.

ratio detector—An FM detector that inherently discriminates against amplitude modulation. Two diodes are connected such that the audio output is proportional to the ratio of the FM voltages applied to them.

Ratio detector.

ratio meter—1. An instrument that measures electrically the quotient of two quantities. It generally has no mechanical control means such as springs. Instead, it operates by the balancing of electromagnetic forces, which are a function of the position of the moving element. 2. Instrument for measuring the ratio of transformation of a transformer by means of a resistance bridge arrangement. 3. Moving-coil type of instrument in which the deflection is proportional to the ratio of the current sent through two coils.

ratio of transformation—The ratio of the secondary voltage of a transformer to the primary voltage under no-load conditions, or the corresponding ratio of currents in a current transformer.

ratio squelch—*See* squelch circuit.

ratio-type telemeter—Also called a position-type telemeter. A telemeter in which the relative phase position between, or magnitude relation of, two or more electrical quantities is the translating means.

rat race—A magic-T modification for the acceptance of higher power. A circular loop of coaxial line closed upon itself and having four branching connections. *See also* hybrid ring.

raw data—1. Data that has not been processed. 2. Data as received, which has not been processed by a machine and which may not yet be in the form that a machine can accept.

raw tape—Also called virgin tape or blank tape. A term sometimes used to describe tape that has not been recorded. *See also* blank tape.

ray—1. A line of propagation of any form of radiant energy. 2. In fiber optics, a straight line, representing light, perpendicular to the light wavefront and traveling in the same direction. At a boundary surface or interface, such as the surface between a fiber core and cladding, the ray may change direction suddenly, but it remains a straight line. 3. A line of light extending between two points.

ray angle—The angle between a light ray and a reference line or plane.

ray-control electrode—An electrode that controls the position of the electron beam on the screen of a cathode-ray tuning-indicator tube.

Raydist—A system using cw transmission to provide hyperbolic lines of position through rf phase comparison techniques. The system is used for surveying or ship positioning in a two-dimensional array. The frequency band is 1.7 to 2.5 MHz. Similar to LORAC in principle.

Rayleigh disc—A special acoustic radiometer used for the fundamental measurement of particle velocity.

Rayleigh distribution—Frequency distribution for an infinite number of quantities of the same magnitude, but of random phase relationships. Sky-wave field intensities follow the Rayleigh distribution for intervals of one minute or less.

Rayleigh distribution (fading)—A statistical distribution describing the magnitude of a phasor composed of the sum of many component phasors randomly distributed in amplitude and phase. Fading of signals caused by cancellation and reinforcement of contributions received over separate paths often exhibits a Rayleigh distribution.

Rayleigh line—In scattered radiation, a spectrum line that has the same frequency as the corresponding incident radiation.

Rayleigh reciprocity theorem—The reciprocal relationship for an antenna when transmitting or receiving. The effective heights and the radiation resistance and pattern are alike, whether the antenna is transmitting or receiving.

Rayleigh scattering—Scattering of radiation by minute particles suspended in air (e.g., by dust).

Rayleigh wave—A surface wave associated with the free boundary of a solid. The wave is of maximum intensity at the surface, but diminishes quite rapidly as it proceeds into the solid.

ray path—An imaginary line, perpendicular to the wavefront, that describes the path along which the energy associated with a point on a wavefront moves.

Raysistor—Raytheon trade name for a device that contains a photosensitive semiconductor element and a light source that can be used to control the conductivity of the semiconductor.

RBOC—Abbreviation for Regional Bell Operating Company. Also called Bell Operating Companies (BOC). Local telephone operating companies that were split off from AT&T and which provide most local and intrastate telephone service in the United States.

RC—Symbol for resistance-capacitance, resistance-coupled, or ray-control electrode.

RC amplifier—Abbreviation for resistance-capacitance coupled amplifier.

RC circuit—A time-determining network of resistors and capacitors in which the time constant is defined as resistance times capacitance.

RC constant—The time constant of a resistor-capacitor circuit, equal in seconds to the resistance value in ohms multiplied by the capacitance value in farads.

RC coupling—*See* resistance-capacitance coupling.

RC filter—*See* resistance-capacitance filter.

RC network—A circuit containing resistances and capacitances arranged in a particular manner to perform a specific function.

RC oscillator—An oscillator in which the frequency is determined by resistance-capacitance elements. *See also* resistance-capacitance oscillator.

RCTL—Abbreviation for resistor-capacitor-transistor logic.

rd—Letter symbol for rutherford.

RDF—Abbreviation for radio direction finder (or finding).

R-display—Essentially an expanded radar A-display in which the trace of an echo can be expanded for more detailed examination.

reach-through voltage—That value of reverse voltage for which the depletion layer in a reverse-biased pn junction spreads sufficiently to make electrical contact with another junction. *See also* punch-through voltage.

reacquisition time—The time required for a tracking radar to relock on the target after the radar's automatic tracking mechanism has been disengaged.

reactance—Symbolized by X . 1. Opposition to the flow of alternating current. Capacitive reactance (X_C) is the opposition offered by capacitors, and inductive reactance (X_L) is the opposition offered by a coil or other inductance. Both reactances are measured in ohms. 2. The opposition offered an alternating flow by a capacitance or inductance related to the frequency of the alternating current. The reactance of a capacitor decreases with increasing frequency, but the reactance of an inductance increases with frequency.

reactance drop—The voltage drop in quadrature with the current.

reactance factor—In a conductor, the ratio of its ac resistance to its ohmic resistance.

reactance frequency multiplier—A frequency multiplier whose essential element is a nonlinear reactor; the nonlinearity of the reactor is used to generate harmonics of a sinusoidal source.

reactance grounded—Grounded through a reactance.

reactance modulator—A modulator whose reactance can be varied in accordance with the instantaneous amplitude of the modulating electromotive force applied. It is normally an electron-tube circuit that usually modulates the phase or frequency.

reactance relay—A form of impedance relay whose operation is a function of the reactance of the circuit.

reactance tube (transistor)—A vacuum tube or transistor connected so as to appear as a reactance to the rest of the circuit. This is accomplished by deriving the grid (base) excitation from the plate (collector) voltage through an RC network that changes its phase by approximately 90°. Thus, since the plate (collector) current is in phase with the grid (base) excitation, the tube (transistor) draws an apparently reactive current. The magnitude of the apparent reactance is controlled by variation of the gain of the tube (transistor).

reactivation—Application of an above-normal voltage to a thoriated filament for a few seconds to bring a fresh layer of thorium atoms to the filament surface and thereby improve electron emission.

reactive—Pertaining to either inductive or capacitive reactance. A reactive circuit has a higher reactance than resistance.

reactive attenuator—An attenuator that dissipates almost no energy.

reactive balance—1. The capacitive or inductive balance that is often required to null the output of certain transducers or systems when the excitation and/or the output is given in terms of alternating current. 2. The condition of an ac circuit when the phase angle between the voltage and current is zero. 3. The amount of corrective capacitance or inductance required to null the output of certain transducers or systems having ac excitation.

reactive factor—The ratio of reactive power to total power in a circuit.

reactive-factor meter—An instrument for measuring reactive factor.

reactive load—A load having reactance (i.e., a capacitive or inductive load), as opposed to a resistive load.

reactive near-field region—That region of the field of an antenna immediately surrounding the antenna wherein the reactive field predominates.

reactive power—Also called wattless power. The reactive voltage times the current, or the voltage times the reactive current, in an ac circuit. Unit of measurement is the var.

reactive power flow—The component of energy lost over transmission lines due to reactive power.

reactive sputtering—A sputtering technique that involves the introduction of reactive gases such as oxygen, nitrogen, and hydrogen into the glow discharge so that oxides, nitrides, and hydrides of the evaporant are deposited on the substrate.

reactive voltampere—See voltampere reactive.

reactive voltamperehour meter—See varhour meter.

reactive voltampere meter—See varmeter.

reactor—A physical device used primarily to introduce reactance or susceptance into a branch.

reactor-start motor—A form of split-phase motor designed for starting with a reactor in series with the main winding. The reactor is short-circuited (or otherwise made ineffective) and the auxiliary circuit is opened as soon as the motor attains a predetermined speed.

read—In a computer: 1. To copy, usually from one form of storage to another. 2. To sense the meaning of an arrangement of hardware representing information. 3. To exact information. 4. To transmit data from an input device to a computer. 5. To sense the presence of information in some type of storage, which includes RAM, magnetic tape, punched tape, etc.

readability—The ability to be understood—specifically, the understandability of signals sent by any means of telecommunications.

read-around—See read-around ratio.

read-around ratio—Also called read-around. In electrostatic storage tubes, the number of successive times information can be recorded as an electrostatic charge on a single spot in the array without producing the necessity for restoring the charge on surrounding spots.

reader—1. In a computer, a device that converts information in one form of storage to information in another form of storage. 2. Any device capable of transcribing data from an input medium.

read head—In a computer, a device that converts digital information stored on a magnetic tape or on a drum into electrical signals usable by computer arithmetic.

read in—To sense information in a source and transmit it to an internal storage.

reading access time—In a computer, the time before a word may be used during the reading cycle.

reading rate—1. In a computer, the number of characters, cards, etc., that can be sensed by an input unit in a given time. 2. In a digital meter, the number of successive readings (including measurement and display) performed per second, on a continuous basis.

read-in program—A program that itself can be put into a computer in simple binary form but that makes it possible for other programs to be read into the computer in more complex forms.

read-mainly memory—See RMM.

read-mostly memory—An integrated array of amorphous and crystalline semiconductor devices that is capable of being programmed, read, and reprogrammed repeatedly. Once reprogrammed, this type of memory retains data unless it is altered intentionally.

read-only memory—Acronym: ROM. 1. A digital memory that, after its initial programming by the manufacturer, can only be read and no longer written on; a permanent memory. 2. A memory that cannot be altered in normal use of a computer. Usually a small memory that contains often-used instructions such as microprograms or system software as firmware. Peripheral equipment uses ROM for character generation, code translation, and for designing peripheral processors. 3. A memory in which information is stored permanently, e.g., a math function or a microprogram. A ROM is programmed according to the user's requirements during memory fabrication and cannot be reprogrammed. A ROM is analogous to the dictionary, in which a certain address results in predetermined information output. 4. A digital building block usually classified as a memory type that contains information permanently written into it during manufacture that can be read at the outputs but not changed. 5. A random-access storage in which the data pattern is unchangeable after manufacture. 6. A computer memory that can be written into during manufacture or installation, but is only read out after that. The read-only memory is usually a nonvolatile form of memory. 7. A storage arrangement primarily for information-retrieval applications. The information may be wired in when the storage device is made, or it may be written in at a speed much less than the retrieval speed. 8. A digital storage device specified for a single function. Data is loaded permanently into the ROM when it is manufactured. This data is available whenever

the ROM address lines are scanned. 9. A memory in which the contents are not intended to be altered during normal operation. The term read-only memory implies that the content is determined by its structure and is unalterable (e.g., mask programmable ROM). Most ROMs are $n \times 8$ (words \times bits/word) to work with popular microprocessors. There are also special-purpose ROMs, such as character generators, with a 7-bit-wide output word and addressing structure to output one-hundred twenty-eight 9×7 characters.

readout—1. The manner in which a computer displays processed information—e.g., digital visual display, punched tape, automatic typewriter, etc. *See also* display. 2. The information extracted from a memory device, such as a program store or call store. 3. The visual display of the output of a measuring instrument, or of a memory, or of a computer.

readout device—In a computer, a device, consisting usually of physical equipment, that records the computer output either as a curve or as a set of printed numbers or letters.

readout equipment—The electronic apparatus that provides indications and/or recordings of transducer output.

readout station—A recording or receiving radio station at which information is received as it is read out by the transmitter in a missile, probe, satellite, or other spacecraft. (The same station may serve also as a tracking station.)

read pulse—1. A pulse applied to one or more binary cells to determine whether a bit of information is stored there. 2. A pulse that causes information to be read out of a memory cell.

readthrough—The continuous recovery in an audio channel of the target modulation, making possible rapid evaluation of the effectiveness of a jamming effort.

read time—More commonly called access time. With respect to a memory, the interval between the time the read control and the address or location are present and the time the data output changes state.

read/write check indicator—A device incorporated in some computers to indicate, on interrogation, whether there was an error in reading or writing. The machine can be made to stop, attempt the operation again, or follow a special subroutine, depending on the result of the interrogation.

read/write cycle—The sequence of operations required to read and write (restore) memory data.

read/write cycle time—*See* cycle time.

read/write head—1. The device that reads and writes information on tape, drum, or disk storage devices. 2. The mechanism that writes data to or reads data from a magnetic recording medium. 3. An electromagnet capable of producing a switchable magnetic field to read and record bit streams.

read/write memory—1. A memory whose contents can be continuously changed quickly and easily during system operation. It differs from a read-only memory (ROM), whose contents are fixed and not subject to change, and a reprogrammable ROM, whose contents can be changed but only periodically. 2. A memory in which each cell may be selected by applying appropriate electrical input signals, and the stored data may be either (a) sensed at appropriate output terminals, or (b) changed in response to other similar electrical input signals.

ready-to-receive signal—In a facsimile system, a signal returned to the transmitter to indicate that the receiver is ready to accept a transmission.

real estate—Slang for the area on a printed circuit board or the surface of a wafer on which circuits can be built.

real power—The component of apparent power that represents true work in an ac circuit. It is expressed in watts and is equal to the apparent power times the power factor.

real time—1. Having to do with the actual time during which physical events take place. 2. The performance of a computation during the actual time that the related physical process transpires in order that results of the computations are useful in guiding the physical process. 3. Refers to a type of operating system that supports online equipment having critical time constraints. Events must be handled promptly (within set timing limits). Most process control and military command/control systems are real-time systems. 4. A computer process executed with sufficient speed so that the results of a process being monitored appear to be presented instantaneously. The computer generally is able to present the results with sufficient speed to permit control changes to be made. *See* closed loop; open loop. 5. A computation or process by a computer using inputs derived from time-initiated events; the output resulting from the computation or processing can have an effect on and/or predict trends concerning those events. 6. Responding instantaneously, rather than delayed by transmission format. 7. The operation of a program in the same time frame as a human being would.

real-time clock—1. A clock that indicates the passage of actual time, such as elapsed time in the flight of a missile, as opposed to some fictitious time established by a computer program. 2. A system clock that indicates actual elapsed time from some reference time (e.g., noon). 3. A timing device used by a computer to derive elapsed time between events and to control processing of time-initiated event data. 4. A device that measures time at a rate consistent to the tasks being performed. Sometimes used for pacing the occurrence of events within a system.

real-time data processing—The processing of transactions as they occur, rather than batching them.

real-time executive—1. Supervisory software that allocates system resources among several tasks to allow them to perform necessary calculations in real time. The executive has responsibility for all priority scheduling, interrupt handling, timer service, physical control, inter-program communication, and queue maintenance required by real-time applications. 2. An operating system that runs the system in a real-time mode, typically required by online data communications or process-control systems.

real-time input—Input information inserted into a system at the time it is generated by another system.

real-time operating system—Operating system capable of real-time task management. Includes event scheduling, interrupt management, and real-time event counters.

real-time operation—1. Operations performed on a computer in time with a physical process so that the answers obtained are useful in controlling that process. 2. The use of a computer to control a process as it is actually occurring, necessitating, in general, relatively rapid operation on the part of the computer. 3. Data-processing technique in which information is utilized as events occur and the information is generated, as opposed to batch processing at a time unrelated to the time the information was generated.

real-time output—Output information removed from a system at the time it is needed by another system.

real-time reaction—A computer function that immediately responds to, or causes, a physical application action.

real-time spectrum analyzer—A device in which analysis of the spectrum of the incoming signal is

performed continuously, with the time sequence of events preserved between input and output.

real-time system— 1. A computer system in which data processing is performed so that the results are available in time to influence the controlled or monitored process. 2. An information system whose input or output rate is not controlled by the system, but depends on external factors. 3. A system in which transactions are processed as they occur.

rear projection— A projection television system in which the picture is projected on a ground-glass screen to be viewed from the opposite side of the screen.

rear suspension— In moving-coil speakers, a pliable support situated near the apex of the cone. Assists in keeping the coil in a concentric position in the air gap between the magnet poles.

rebatron— A relativistic electron-bunching accelerator that produces a very tightly bunched beam with little velocity modulation, but high harmonic content. The beam can be used to excite structures that are large compared to a wavelength.

Rebecca— An airborne interrogator-responder of the British Rebecca-Eureka navigation system. It can also be used with a special ground beacon known as Babs to provide low-approach facilities.

Rebecca-Eureka system— A British radar navigational system employing an airborne interrogator (Rebecca) and a ground transponder beacon (Eureka). It provides homing to an airfield from distances of up to 90 miles (145 km).

rebond— A second bonding attempt after a bond has been removed or failed to bond on the first attempt.

rebonding-over bond— A second bond made on top of a removed or damaged bond or a second bond immediately adjacent to the first bond.

reboot— 1. To restart a computer by reloading the operating system. 2. To restart a computer after it has been operating for some time, usually in an attempt to clear an error condition.

rebroadcast— The reception and the simultaneous or subsequent retransmission of a radio or television program by a broadcast station.

recalcrescent point— The temperature at which heat is suddenly liberated as the temperature of a heated metal drops.

recall— In a calculator, to retrieve from a register a previously entered number, for checking or use in further calculations.

receive current— The amount of current drawn by a transceiver when receiving radio signals.

received power— The power of a returned target signal received at the radar antenna.

received signal level— The strength of an intercepted radio signal at the antenna terminals of the receiver, expressed in microvolts or dBm.

receive only— Abbreviated RO. A teletypewriter-type terminal having no keyboard or tape reader.

receive-only typing reperforator— Also called rotor. A teletypewriter receiver whose output is a perforated tape that has characters along the edge of the tape.

receiver— 1. The portion of a communications system that converts electric waves into a visible or audible form. 2. An electromechanical device for converting electrical energy into sound waves. *See also* earphone. 3. A device for the reception and, if necessary, demodulation of electronic signals. 4. The electromagnetic unit in a telephone handset used to convert electrical energy to sound energy.

receiver bandwidth— The spread in frequency between the half-power points on the response curve of a receiver.

receiver gating— Application of operating voltages to one or more stages of a receiver only during the part of a cycle when reception is desired.

receiver images— Undesired signals in a receiver caused by the heterodyning process.

receiver incremental tuning— A control feature to permit receiver tuning (of a transceiver) up to 3 kHz to either side of the transmitter frequency.

receiver lockout system— In mobile communications, an arrangement of control circuits whereby only one receiver can feed the system at one time, to avoid distortion.

receiver noise figure— The ratio of noise voltage in a given receiver to that of a theoretically perfect receiver.

receiver noise threshold— The level that must be exceeded by the minimum discernible signal. External noise reaching the front end of a receiver and the noise added by the receiver itself determine the noise threshold.

receiver primaries— Constant-chromaticity, variable-luminance colors that are produced by a television receiver and that when mixed in proper proportions produce other colors. Usually three primaries—red, green, and blue—are used.

receiver radiation— Radiation of interfering electromagnetic signals by any oscillator of a receiver.

receiver sensitivity— The lower limit of useful signal input to the receiver. It is set by the signal-to-noise ratio at the output.

receiving amplifier— The amplifier used at the receiving end of a system to raise the level of the signal.

receiving antenna— A device for converting received space-propagated electromagnetic energy into electrical energy.

receiving circuit— An apparatus and connections used exclusively for the reception of messages at a radiotelephone or radiotelegraph station.

receiving equipment— The equipment (amplifiers, filters, oscillator, demodulator, etc.) associated with incoming signals.

receiving-loop loss— That part of the repetition equivalent assignable to the station set, subscriber line, and battery-supply circuit on the receiving end of a telephone line.

receiving margin— Also called range or operating range. In telegraphy, the usable range of adjustment of the range finder; for a machine that is adjusted properly, approximately 75 points on a 120-point scale.

receiving perforator— In printing telegraph systems, an apparatus that punches a paper strip automatically in accordance with the arriving signals. When the paper strip is later passed through a printing telegraph machine, the signals will be reproduced as printed messages, ready for delivery to the customer.

receptacle— 1. Usually the fixed or stationary half of a two-piece multiple-contact connector. Also, the connector half usually mounted on a panel and containing socket contacts. 2. A contact device installed at the outlet. Allows the connection of external electric cords from lamps or appliances.

receptacle connector— An electrical connector intended to be mounted or installed onto a fixed structure, such as a panel, electrical case, or chassis, and which couples or mates to a plug connector.

reception— Listening to, copying, recording, or viewing any form of emission.

rechargeable— Capable of being recharged. Usually used in reference to secondary cells or batteries.

rechargeable primary cell—A cell that is ordinarily used in one-shot service, but which is capable of a limited number of charge/discharge cycles.

reciprocal—The number 1 (unity) divided by a quantity; e.g., the reciprocal of 2 is $1/2$; of 4, $1/4$, etc.

reciprocal-energy theorem—If an electromotive force E_1 in one branch of a circuit produces a current I_2 in any other branch, and if an electromotive force E_2 inserted into this other branch produces a current I_1 in the first branch, then $I_1E_1 = I_2E_2$.

reciprocal ferrite switch—A ferrite switch that can be placed in a waveguide to route an input signal to either of two output waveguides. Switching is accomplished by a Faraday rotator under the influence of an external magnetic field.

reciprocal impedance—Two impedances Z_1 and Z_2 are said to be reciprocal impedances with respect to an impedance Z (invariably a resistance) if they are so related as to satisfy the equation $Z_1Z_2 = Z^2$.

reciprocal transducer—A transducer that satisfies the principles of reciprocity—i.e., if the roles of excitation and response are interchanged, the ratio of excitation to response will remain the same.

reciprocation—The process of deriving a reciprocal impedance from a given impedance or finding a reciprocal network for a given network.

reciprocity theorem—In any system composed of linear bilateral impedances, if an electromotive force E is applied between any two terminals and the current I is measured in any branch, their ratio (called the transfer impedance) will be equal to the ratio obtained if the positions E and I are interchanged.

reclosing relay—Any voltage, current, power, etc., relay that recloses a circuit automatically.

recognition device—A device that can identify any number of a set of distinguishable entities.

recognition differential—For a specified listening system, the amount by which the signal level exceeds the noise level that is presented to the ear when a 50 percent probability of detection of the signal exists.

recombination—1. A collision within a semiconductor crystal lattice of a conduction-band electron and a valence-band hole. The ability of each to function as a current carrier is lost, due to mutual cancellation, so that a recombination effectively destroys the hole-electron carrier pair. 2. A process in which current carriers of opposite signs combine and form stable, neutral entities, resulting in zero net charge.

recombination coefficient—The quantity that results from dividing the time rate of recombination of ions in an ionized gas by the product of the positive-ion density and the negative-ion density.

recombination radiation—The radiation produced in a semiconductor when electrons in the conduction band recombine with holes in the valence band. If an actual population inversion between portions of the valence and conduction bands (or between adjacent localized states of acceptors or donors near these bands) is achieved, stimulated emission and laser amplification or oscillation can take place. This is the radiation process of importance in injection lasers.

recombination velocity—On a semiconductor surface, the normal component of the electron (or hole) current density at the surface divided by the excess electron (or hole) charge density at the surface.

reconditioned-carrier reception—Also called exalted-carrier reception. Reception in which the carrier is separated from the sidebands in order to eliminate amplitude variations and noise, and then is increased and added to the sidebands in order to provide a relatively

undistorted output. This method is frequently employed with a reduced-carrier signal-sideband transmitter.

record—1. A character or characters that are grouped together in the flow of data in a system; for example, one line of type of the contents of a punched card. A record may be of fixed length, as with punched cards, or of variable length, as with a line of type. 2. A group of related facts or fields of information handled as a unit; thus a listing of information, usually printed or in printable form. 3. The process of putting data into a computer storage device. 4. To preserve for later reproduction. 5. Relating to data that is treated as a unit of logical information. The delineation of a record may be arbitrary and determined by the designer of the information format. (A record may be recorded on all or part of a block or more than one block.) 6. A collection of related items of data (fields) treated as a unit.

record changer—1. A device that will automatically play a number of phonograph records in succession. 2. A type of automatic turntable capable of playing a number of records (usually 6 to 10) in sequence.

record code—A special control code used to mark the separation between adjacent records.

record compensator—Also called a record equalizer. An electrical network that compensates for different frequency-response curves in various recording techniques.

recorded tape—Also called a prerecorded tape. 1. A tape that contains music, dialogue, etc., and is sold to audiophiles and others for their listening pleasure. 2. A commercially available recorded tape.

recorded value—The value recorded by the marking device on a chart with reference to the division lines marked on the chart.

recorded wavelength—In a phonograph record, the length of groove required for a signal of given frequency to complete one cycle. At any particular distance from the record center, i.e., at a particular groove velocity, the recorded wavelength decreases with increasing frequency. Similarly for a given frequency, the recorded wavelength decreases with progress toward the record center (i.e., as groove velocity decreases).

record equalizer—See record compensator.

recorder—Also called recording instrument. 1. An instrument that makes a permanent record of varying electrical impulses—e.g., a code recorder, which punches code messages into a paper tape; a sound recorder, which preserves music and voices on disc, film, tape, or wire; a facsimile recorder, which reproduces pictures and text on paper; and a video recorder, which records television pictures on film or tape. 2. A device that makes a record of changes in varying electrical quantities or signals. 3. An instrument that makes a graphic record of the value of one or more quantities as a function of another variable (usually time).

record gap—In a computer, a space between records on a tape. It is usually produced by acceleration or deceleration of the tape during the write operation.

recording ammeter—An ammeter that provides a permanent recording of the value of either an alternating or a direct current.

recording blank—See recording disc.

recording channel—One of several independent recorders in a recording system, or independent recording tracks on a recording medium.

recording curve—See equalization.

recording demand meter—Also called demand recorder. An instrument that records the average value of the load in a circuit during successive short periods.

recording density—The number of bits recorded per unit of length in a single linear track in a recording medium.

recording disc—Also called a recording blank. A (unrecorded) disc made for recording purposes.

recording head—A magnetic head that transforms electrical variations into magnetic variations for storage on magnetic media. *See also* cutter.

recording instrument—Also called a recorder or graphic instrument.

recording lamp—A light source used in the variable-density system of sound recording on movie film. Its intensity varies in step with the variations of the audio-frequency signal sent through it.

recording level—The amplifier output required to provide a satisfactory recording.

recording-level meter—An indicator on a tape or disc recorder that provides some idea of the signal levels being applied to the recording medium from moment to moment. It is intended as an aid in setting the recording levels to ensure that the tape or disc is neither overloaded with excessive levels or under-recorded with too little signal, allowing hiss and other noise to intrude. Recording-level meters come in a variety of types, including meters that register the approximate average value of the signal (of which the professional vu meter is an example), those designed to show the instantaneous peak levels of the signal, and some not readily classifiable into any specific group.

recording loss—In mechanical recording, the loss that occurs in the recorded level because the amplitude executed by the recording stylus differs from the amplitude of the wave in the recording medium.

recording noise—Noise induced by the amplifier and other components of a recorder.

recording preamplifier—*See* preamplifier.

recording-reproducing head—A dual-purpose head used in magnetic recording.

recording spot—An instantaneous area acted on by the registering system of a facsimile recorder.

recording storage tube—A type of cathode-ray tube in which the equivalent of an image can be stored in the form of a pattern of electrostatic charge on a storage surface. There is no visual display, but the stored information can be read out at any later time in the form of an electric output signal.

recording stylus—The tool that inscribes a groove into the recording medium.

recording trunk—A trunk that extends between a local central office or private branch exchange and a toll office and that is used only for communication with toll operators and not for the completion of toll connections.

recording voltmeter—A voltmeter that provides a permanent record of the value of either alternating or direct voltage.

record layout—The arrangement and structure of information in a record, including the sequence and size of the components. By extension, the description of such an arrangement.

record length—A measure of the size of a record, usually expressed in terms of such units as words or characters.

record mark—A means of marking the separation between adjacent records: on magnetic tape, a record gap; on paper tape, a record code; in data transmission, a record pause. Often, the record code is used along with a gap or a pause to allow for different devices throughout a data-transmission system, each of which can recognize only one of the three types of record marks.

record medium—In a facsimile recorder, the physical medium onto which the image of the subject copy is formed.

record player—A motor-driven turntable, pickup arm, and stylus for converting the signals impressed onto a phonograph record into a corresponding audio-frequency voltage. This voltage is then applied to an amplifier (usually contained within the record player cabinet) for amplification and conversion to sound waves.

record/play head—A single magnetic-tape head that is used for recording and playback of a tape.

record separator—A character intended as an identifier of a logical boundary between records.

record sheet—In a facsimile recorder, a sheet or medium upon which the image of the subject copy is recorded.

recover—To restore the computer to a previous state.

recovered audio—The value of the audio voltage measured at the detector output under the specified circuit conditions.

recovered charge—The total charge recovered from the diode after switching from a specified forward current condition to a specified reverse condition. This charge includes components due to both carrier storage and depletion-layer capacitance.

recovered voice quality—Quality of the voice signal after the process of decoding or scrambling.

recovery—1. In an electronic device, the time required to enable the device to react to new signals. 2. In fluidic devices, a generally percentile representation of output capture as related to supply, such as output pressure versus input pressure. 3. The actions required to bring a system to a predefined level of operation after a degradation or failure.

recovery time—1. The time required for a fired atr tube in its mount to deionize to the level at which its normalized conductance and susceptance are within the specified ranges. 2. The time required for the control electrode in a gas tube to regain control after the anode current has been interrupted. 3. In Geiger-Mueller counters, the minimum time from the start of a counted pulse to the instant a succeeding pulse can attain a specified percentage of the maximum amplitude of the counted pulse. 4. The time required for a fired tr or pre-tr tube to deionize to the level at which the attenuation of a low-level radio-frequency signal transmitted through the tube drops to the specified value. 5. In a radar or its component, the time required—after the end of the transmitted pulse—for recovery to a specified relation between receiving sensitivity or received signal and the normal value. 6. Also called response time. The interval required, after a sudden decrease in input-signal amplitude to a system or component, for a specified percentage (usually 63 percent) of the ultimate change in amplification or attenuation to be attained. 7. In thermal time-delay relay, the cooling time required from heater deenergization to reenergization such that the new time delay is 85 percent of that exhibited from a cold start. 8. Also called response time. In a power supply, the time required for recovery of the load voltage from a step change in load current or line voltage. 9. The length of time that a condition remains in effect after the control signal that initiated the effect has disappeared.

rectangular array—1. Multiple copies of an entity at intervals of vertical and horizontal spacing, e.g., a matrix. 2. *See* matrix.

rectangular-loop material—A material that has a rectangular hysteresis loop, i.e., the difference between the coercive force and the magnetizing force at saturation induction is small.

rectangular scanning—A two-dimensional sector scan in which a slow sector scan in one direction is superimposed perpendicularly onto a rapid sector scan.

rectangular wave—A periodic wave that alternately assumes one of two fixed values, the time of transition being negligible in comparison with the duration of each fixed value.

rectangular waveguide—A hollow enclosure of rectangular cross section, normally with the dimensions of the sides in a ratio of 2:1. With dimensions so proportioned, the dominant mode has a free-space wavelength range between one and two times the longer side dimension. Rectangular waveguides normally can be used only over less than octave ranges.

Rectangular waveguide.

Rectenna—A device that converts microwave power into dc power. It consists of a number of small dipoles, each of which has an associated diode rectifier network connected to a dc bus.

rectification—Conversion of alternating current into unidirectional or direct current by means of a rectifier.

rectification efficiency—Ratio of the direct-current power output to the alternating-current power input of a rectifier.

rectification factor—The change in average current of an electrode divided by the change in amplitude of the alternating sinusoidal voltage applied to the same electrode, the direct voltages of all electrodes being maintained constant.

rectified value—The average of all the positive or negative values of an alternating quantity over a whole number of periods.

rectifier—1. Device having an asymmetrical conduction characteristic employed in a way to convert alternating current into unidirectional current. In amplitude-modulation detection, recovery of original signals is frequently accomplished by a rectifier. 2. Device that converts alternating current into unidirectional current by permitting appreciable current in one direction only. 3. A two-element tube or a solid-state device that is used to convert alternating current to direct current. Usually rated above one-half ampere.

rectifier diode—A diode that exhibits an asymmetrical voltage-current characteristic and is used for current and voltage rectification.

rectifier instrument—The combination of an instrument sensitive to direct current and a rectifying device whereby alternating currents or voltages can be measured.

rectifier meter—*See* rectifier instrument.

rectifier stack—A dry disc rectifier made up of layers of individual rectifier discs (e.g., a selenium or copper-oxide rectifier).

rectifier transformer—A transformer whose primary operates at the fundamental frequency of the ac system and whose secondary has one or more windings conductively connected to the main electrodes of the rectifier.

rectifying element—A circuit element that conducts current in one direction only.

rectigon—A hot-cathode gas-filled diode that operates at a high pressure. Used most frequently in battery-charging circuits.

rectilinear compliance—A mechanical element that opposes a change in the applied force (e.g., the springiness that opposes a force on the diaphragm of a speaker or microphone).

rectilinear—In a straight line; specifically, moving, forming, or bounded by a straight line.

rectilinear scanning—The scanning of an area in a predetermined sequence of narrow, straight, parallel strips.

rectilinear writing recorder—An oscillograph that records in rectilinear coordinates.

recoverability—The ability to continue operating after partial or complete loss of the primary communications facility.

recurrence rate—*See* repetition rate, 1.

recursion—The continuous repeating of the same operation or group of operations.

recursive—Capable of being repeated.

recursive filter—*See* digital filter.

recyclability—The capability of a battery system to be recharged after it has been discharged.

recycling modulo- n counter—A counter that has n distinct states and that counts to a maximum number and returns, when the next input pulse is applied, to its minimum number.

red gun—In a three-gun color television picture tube, the electron gun whose beam strikes only the phosphor dots that emit the red primary.

redistribution—In a charge-storage tube or television camera tube, the alteration of charges on one area of a storage surface by secondary electrons from any other area of the same surface.

redox cell—A cell designed to convert the energy of the reactants to electrical energy. An intermediate reductant, in the form of a liquid electrolyte, reacts at the anode in a conventional manner; it is then regenerated by reaction with a primary fuel.

red-tape operation—In a computer, operations that do not directly contribute to the results, i.e., those internal operations that are necessary to process data, but do not in themselves contribute to any final answer.

reduced generator efficiency—The ratio of a given thermoelectric-generator efficiency to the corresponding Carnot efficiency.

reduced instruction set computer—Abbreviated RISC. A CPU in which processing capabilities have been reduced to increase speed.

reduced telemetry—Telemetry data transformed from raw form into a usable form.

reduction technique—A technique for simplifying or restructuring a Boolean expression for easier, lower-cost implementation in circuitry.

redundancy—1. The employment of several devices, each performing the same function, in order to improve the reliability of a particular function. 2. Added or repeated information employed to reduce ambiguity or error in a transmission of information. As the signal-to-noise ratio decreases, redundancy may be employed to prevent an increase in transmission error. 3. In information transmission, the fraction of the total

information content of a message that can be eliminated without losing essential information. 4. The property of having functionally equivalent systems, subsystems, or components in place to back up one another. 5. Also called backup control. A technique that provides a secondary method of control for certain critical functions. 6. The use of additional equipment and facilities to provide for continuity of service during trouble situations. 7. A method of ensuring higher reliability or performance in which more than one of the same item is used. 8. A configuration of multiple elements that can still produce a correct output when one or more elements are not functioning correctly.

redundancy check—In a computer, an automatic or programmed check that makes use of components or characters inserted especially for checking purposes.

redundant code—A code that uses more signal elements than are necessary to represent the intrinsic information.

redundant data—1. Data that is not necessary for the information content of a transmission but is usually added to transmitted information to aid in the detection of communications errors. 2. A data sample so similar to the preceding sample from the same source that it is of no interest in connection with subsequent analysis of the experiment or test, except for the fact of the similarity.

red video voltage—The signal voltage that controls the grid of the red gun in a three-gun picture tube. This signal is a reproduction of the output from the red camera at the transmitter.

reed—A thin bar located in a narrow gap and made to vibrate electrically, magnetically, or mechanically by forcing air through the gap.

reed frequency meter—See vibrating-reed meter.

reed relay—1. A relay in which two flat magnetic strips mounted inside a coil are attracted to each other when the coil is energized. The relay contacts are mounted on the strips. 2. A device that uses two (sometimes three) strips of magnetizable metal, enclosed in glass, as the contacts. The control member is a coil surrounding the glass capsule. 3. One or more reed switches operated by a single coil. 4. An assembly that combines a reed switch with an electromagnetic operating coil. 5. An electromechanical relay based on the use of a reed switch, an assembly of partially overlapping magnetic metal strips or reeds hermetically sealed in a glass tube. In the influence of a magnetic field, the contact ends of the reeds may be caused to open or close. This permits extremely fast making or breaking of an external circuit. It is important to distinguish between a reed switch and a reed relay. Reed switches, as in keyboards, normally depend on the motion of an external permanent magnet moved with respect to the glassed reed capsule. By contrast, reed relays are assemblies of the glassed reed capsule within a coil or solenoid.

reed switch—A type of magnetic switch consisting of contacts formed by two thin, movable, magnetically actuated metal vanes or reeds, held in a normally open position within a sealed glass envelope.

Reed switch.

reel-to-reel—See open-reel.

reentrancy—1. A type of feedback employed in microwave oscillators. In most magnetrons, a circuit is used that can be described as a slow-wave structure that feeds back into itself. In beam reentrancy, the beam may be circulated repeatedly through the interaction space. 2. That characteristic of a computer subroutine that permits a second task to enter the subroutine before completion of its execution by the first task.

reentrant cavity—A resonant cavity in which one or more sections are directed inward with the result that the electric field is confined to a small area or volume.

reentrant code—1. The instructions forming a single copy of a program or subroutine that is shared by two or more programs, as opposed to the conventional method of embedding a copy of a subroutine within each program. Characteristically, reentrant routines are composed completely of instructions and constants that are not subject to modification during execution. 2. Code that may be executed simultaneously by more than one task. Thus, the code cannot be self-modifying, and each task must maintain its own data area. This does not imply that tasks will actually execute the code simultaneously, although this could occur in a multiprocessor system. 3. A program task or routine that can be executed simultaneously by more than one process.

reentrant program—A subroutine written in such a way that it can be used by many users concurrently. (The alternative is to let each user have his or her own copy of the program, which uses up a lot of memory space.) A reentrant program cannot be allowed to modify its own instructions.

reentrant subroutines—Computer subroutines that can be executed from any of several application programs operating on different levels of priority.

reentrant winding—An armature winding that returns to its starting point, thus forming a closed circuit.

reference acoustic pressure—Also called reference sound level. That magnitude of a complex sound that produces a sound-level meter reading equal to the reading that results from a sound pressure of 0.0002 dyne per square centimeter at 1000 hertz.

reference address—An address used in digital-computer programming as a reference for a group of relative addresses.

reference angle—The angle formed between the center line of a radar beam as it strikes a reflecting surface and the perpendicular drawn to that reflecting surface.

reference black level—1. The picture-signal level corresponding to a specified maximum limit for black peaks. 2. The maximum negative-polarity amplitude of the video signal.

reference boresight—A direction defined by an optical, mechanical, or electrical axis of an antenna, established as a reference for the purpose of beam direction or tracking axis alignment.

reference burst—See color burst.

reference dipole—A half-wave straight dipole tuned and matched for a given frequency and used as a unit of comparison in antenna measurement work.

reference electrode—In pH measurements, an electrode, usually hydrogen-filled, used to provide a reference potential. See also glass electrode.

reference frequency—A frequency coinciding with, or having a fixed and specified relation to, the assigned frequency. It does not necessarily correspond to any frequency in an emission.

reference language—The definitive description of a programming language, completely specifying all its concepts and the relations between them. It may be in

English, or the language itself may be the reference language.

reference level—The starting point for designating the value of an alternating quantity or a change in it by means of decibel units. For sound loudness, the reference level is usually the threshold of hearing. For communications receivers, 60 microwatts is normally used. A common reference in electronics is 1 milliwatt, and power is stated as so many decibels above or below this figure.

reference line—A line from which angular measurements are made.

reference monitor—A receiver (or other similar device of known performance capabilities) used for judging the transmission quality.

reference noise—The magnitude of circuit noise that will produce a noise-meter reading equal to that produced by 10^{-12} watt of electric power at 1000 hertz.

reference oscillator—The high stability, usually crystal and temperature controlled, rf signal source used as a phase reference in phase-locked oscillators.

reference phase—The phase of the color burst transmitted with color-television carriers. It is used in synchronizing the receiver reference oscillator with the transmitted color signals.

reference point—1. A terminal that is common to both the input and the output circuits. 2. The point of a chromaticity diagram that represents the chromaticity of a reference stimulus.

reference record—In digital-computer programming, a compiler output that lists the operations and their positions in the final specific routine, plus information describing the segmentation and storage allocation of the routine.

reference recording—A recording of a radio program for future reference or checking.

reference signal—A stable signal used as a standard against which other variable signals may be compared and adjusted.

reference sound level—See reference acoustic pressure.

reference time—In a computer, an instant chosen near the beginning of switching as an origin for time measurements. It is taken as the first instant at which either the instantaneous value of the drive pulse, the voltage response of the magnetic cell, or the integrated voltage response reaches a specified fraction of its peak pulse amplitude.

reference tone—A stable tone of known frequency continuously recorded on one track of multitrack signal recordings and intermittently recorded on signal-track recordings by the collection-equipment operators for subsequent use by the data analysts as a frequency reference.

reference voltage—Alternating-current voltage in a synchro servosystem used to determine the in-phase or 180° out-of-phase condition to provide directional sense.

reference volume—The magnitude of a complex electric wave, such as that corresponding to speech or music, that gives a reading of 0 vu on a standard volume indicator. The sensitivity of the volume indicator is adjusted so that the reference volume of 0 vu is read when the instrument is connected across a 600-ohm resistance to which there is delivered a power of 1 milliwatt at 1000 hertz.

reference white—The light from a nonselective diffuse reflector as a result of the normal illumination of the scene to be televised.

reference white level—1. In television, the picture-signal level corresponding to a specified maximum limit for white peaks. 2. The maximum positive-polarity amplitude of the video signal.

refiring—Recycling a thick-film resistor through the firing cycle to change the resistor value.

reflectance—1. Ratio of reflected flux to incident flux. Unless otherwise specified, the total reflectance is meant; it is sometimes convenient to divide this into the sum of the specular and the diffuse reflectance. 2. See reflection factor, 2.

reflected impedance—1. The apparent impedance across the primary of a transformer when current flows in the secondary. 2. The impedance at the input terminals of a transducer as a result of the impedance characteristics at the output terminals. 3. The impedance seen at the input of a network when its output is terminated in an impedance of a specified value. (Most often, the network referred to in this connection is a transformer.)

reflected power or signal—The power flowing back to the generator from the load.

reflected resistance—The apparent resistance across the primary of a transformer when a resistive load is across the secondary.

reflected wave—The wave that has been reflected from a surface, a junction of two different media, or a discontinuity in the medium in which it is traveling (e.g., the echo from a target in radar, the sky wave in radio, the wave traveling toward the source from the termination of a transmission line).

Reflected and direct waves.

reflecting curtain—A vertical array of half-wave reflecting antennas placed one-quarter wavelength behind a radiating curtain of dipoles to form a pine-tree array.

reflecting electrode—A tubular outer electrode or the repeller plate in a microwave oscillator tube corresponding in construction but not function to the plate of an ordinary triode. It is capable of generating extremely high frequencies.

reflecting galvanometer—A galvanometer with a small mirror attached to the moving element. The mirror reflects a beam of light onto a scale.

reflecting grating—An arrangement of wires placed in a waveguide to reflect the desired wave while freely passing one or more other waves.

reflection—1. The phenomenon in which a wave that strikes a medium of different characteristics is returned to the original medium with the angles of incidence and reflection equal and lying in the same plane. 2. The change in direction imparted to light rays that impinge on a surface but do not penetrate therein. (Those rays which penetrate are either absorbed as heat energy or refracted within the material.) Equally applicable to other radiation. 3. Return of radiation by a surface, without change in wavelength. The reflection may be specular, from a smooth surface; diffused, from a rough surface or

from within the specimen; or mixed, a combination of the two.

reflection altimeter—An aircraft altimeter that determines altitude by the reflection of sound, supersonic, or radio waves from the earth.

reflection coefficient—1. At the junction of a uniform transmission line and a mismatched terminating impedance, the vector ratios between the electric fields associated with the reflected and the incident waves. 2. At any specified plane in a uniform transmission medium, the vector ratios between the electric fields associated with the reflected and the incident waves. 3. At any specified plane in a uniform transmission line between a source and an absorber of power, the vector ratio between the electric fields associated with the reflected and the incident waves. It is given by the formula

$$\frac{Z_2 - Z_1}{Z_2 + Z_1}$$

where the impedances Z_1 and Z_2 are the impedances of the source and load, respectively. 4. A measure of the difference between the driving-source impedance and the input impedance of a filter. 5. Parametric measurement for elliptical fiber and cable expressed as a ratio of the two-directional flow of power through the cable at any chosen point.

reflection color tube—A color picture tube that produces an image electron reflection in the screen region.

reflection Doppler—A system utilizing the Doppler frequency shift to measure the position and/or velocity of an object not carrying a transponder.

reflection error—In navigation, the error due to the wave energy that reaches the receiver as a result of undesired reflections.

reflection factor—1. Also called mismatch factor, reflectance reflectivity, or transition factor. The ratio of the current delivered to a load whose impedance is not matched to the source to the current that would be delivered to a load of matched impedance. Expressed as a formula:

$$\frac{\sqrt{4Z_1Z_2}}{Z_1 + Z_2}$$

where Z_1 and Z_2 are the unmatched and the matched impedances, respectively. 2. Also called reflectance and reflectivity. A measure of the effectiveness of a surface in reflecting light; the ratio of reflected lumens to the incident lumens.

reflection grating—A wire grating that is placed inside a waveguide so as to reflect a desired wave while at the same time allowing one or more other waves to pass freely.

reflection hologram—A hologram that is illuminated by a source from the viewer's side.

reflection law—For any reflected object, the angle of incidence is equal to the angle of reflection.

reflection loss—1. That part of transmission loss due to the reflection of power at the discontinuity. 2. The ratio (in decibels) of the power incident upon the discontinuity to the difference between the powers incident to and reflected from the discontinuity.

reflection sounding—Echo depth sounding in which the depth is measured by reflecting sound or supersonic waves off the bottom of the ocean.

reflective code—A code that appears to be the mirror image of a normal counting code. The most useful property of reflective codes is that only one digit changes at a time in increasing or decreasing by 1. The reflective binary code is called a Gray code.

reflective jamming—See radar-confusion reflectors.

reflective optics—A system of mirrors and lenses used in projection television.

reflectivity—See reflection factor, 2.

reflectometer—A microwave system arranged to measure the incidental and reflected voltages and indicate their ratio.

reflector—Also called a reflector element. 1. One or more conductors or conducting surfaces for reflecting radiant energy—specifically, a parasitic antenna element located in other than the general direction of the major lobe of radiation. 2. See repeller. 3. An element in a VHF antenna that is situated to the rear of the main dipole. Reflects radio waves onto the dipole. 4. The dish often employed to reflect quiet or distant sounds in an open air setting onto a microphone. 5. A metal plate, metal screen, or any of a group of spaced tuned rods (elements) placed back of the active element of an antenna to make it directive. 6. A type of conducting surface or material used to reflect radiant energy.

reflector element—See reflector.

reflector module—A device containing a light source and a photodetector that detects any object that reflects light produced by the source back to the detector.

reflector satellite—A satellite so designed that radio or other waves bounce off its surface.

reflector voltage—The voltage between the reflector electrode and the cathode in a reflex klystron.

reflex baffle—A speaker baffle in which a portion of the radiation from the rear of the diaphragm is propagated forward after a controlled phase shift or other modification. This is done to increase the overall radiation in some portion of the frequency spectrum.

reflex bunching—In a microwave tube, a type of bunching that is brought about when the velocity-modulated electron stream is made to reverse its direction by means of an opposing dc field.

reflex cabinet—A type of speaker enclosure fitted with a vent or port through which out-of-phase signals from the rear of the cone are "reflexed" by allowing the enclosed air in the cabinet to be tuned for a coupled resonance effect with the cone of the drive unit. The signals are then brought into phase with the front radiation from the cone of the speaker so as to reduce the "boomy" effect of resonance.

reflex circuit—1. A circuit through which the signal passes for amplification both before and after detection. 2. A single stage of amplification that operates on two signals in widely separated frequency ranges.

reflex klystron—A klystron with a reflector (repeller) electrode in place of a second resonant cavity, to redirect the velocity-modulated electrons through the resonant cavity that produced the modulation. Such klystrons are well suited for use as oscillators, because the frequency is easily controlled by repositioning the reflector.

reflowing—The melting of an electrodeposit followed by solidification. The surface has the appearance and physical characteristics of being hot-dipped (especially tin or tin alloy plates).

reflow soldering—A method of soldering involving application of solder, in the form of preforms, paste, or as a solder plate, prior to the actual joining. To solder, the parts are joined and heated, causing the solder to remelt, or reflow. The joint can be made by resistance soldering, hot gas soldering, forced hot air oven, radiant heating, liquid immersion, or condensation soldering.

refracted wave—Also called the transmitted wave. In an incident wave, the portion that travels from one medium into a second medium.

refraction—1. The change in direction of propagation of a wavefront due to its passing obliquely from

one medium into another in which its speed is different. Refraction may also occur in a single medium of varying characteristics. 2. The deflection from a straight path undergone by a light ray passing from one medium into another having a different index of refraction. 3. Light rays that impinge on a surface and thereafter continue through the material or substance generally have their direction of travel altered. This bending constitutes refraction. Example: light entering water from the air. 4. The bending of sound, radio, or light waves as they pass obliquely from a medium of one density to a medium of another density in which their speed is different. 5. The bending of light at the boundary of two surfaces.

Refraction (of radio waves).

refraction error—In navigation, the error due to the bending of one or more wave paths by undesired refraction.

refraction loss—That part of the transmission loss due to refraction resulting from nonuniformity of the medium.

refractive index—Also called index of refraction. 1. Of a wave-transmission medium, the ratio between the phase velocity in free space and in the medium. 2. The ratio of the velocity of light in a vacuum to its velocity in a material, such as a fiber. Also, the ratio of the sine of the angle of incidence of light on the material to the angle of refraction of the light. The refractive index of any material varies with the wavelength of light. In a fiber, core refractive index must be greater than that of the cladding.

refractive modulus—Also called the excess modified index of refraction. The excess over unity of the modified index of refraction. It is expressed in millionths and is given by the equation

$$M = (n + h/a - 1)10^6$$

where

M = the refractive modulus,
 n = the index of refraction at a height H above sea level, and
 a = the radius of the earth.

refractivity—Ratio of phase velocity in free space to that in the medium, minus 1.

refractometer—An instrument for measuring the refractive index of a liquid or solid, usually from the critical angle at which total reflection occurs.

refractor metal—A metal that has an extremely high melting point; in the broad sense, a metal that has a melting point above those of iron, nickel, and cobalt.

refractory metal-oxide semiconductor—See RMOS.

refrangible—Capable of being refracted.

refresh—1. The periodic renewing of data, or data-carrying electrical charges, in a semiconductor memory. The data in various semiconductor memories would quickly be lost if this action were not taken periodically. 2. CRT display technology requiring continuous restroking of the display image. 3. Repeated writing of display frames of a CRT display surface. Since the image is retained by nonstoring phosphor for only short intervals, it must be continually rewritten (refreshed) in order to remain visible.

refresh cycle—The periodic recharging of the capacitors in a dynamic RAM (DRAM) array.

refresh display—A CRT device that requires the refresh of its screen presentation at a high rate in order that the image will not fade or flicker. The refresh rate is proportional to the decay rate of the phosphor. Refresh displays require continuous interaction with the host computer and display controller.

refresh rate—The number of times per second that a complete image is formed on the screen by a monitor or TV. Refresh rate is proportional to the decay rate of a monitor's phosphor compound. A slow-decay phosphor produces bright images, but often a ghosting effect as well. A fast-decay phosphor's images leave no such trailing effect, but are not as bright and may flicker. Refresh rates less than 70 Hz produce an annoying flicker, which can contribute to eye strain.

refresh time interval (refresh period)—The time between the successive refresh operations that are required to restore the charge in a dynamic memory cell.

regeneration—Also called regenerative feedback and positive feedback. 1. The gain in power obtained by coupling from a high-level point back to a lower-level point in an amplifier or in a system that encloses devices having a power-level gain. 2. In a computer storage device whose information storing state may deteriorate, the process of restoring the device to its latest undeteriorated state. See also rewrite. 3. The replacement of a charge in a charge-storage tube to overcome decay effects, including a loss of charge by reading.

regeneration control—A variable capacitor, variable inductor, potentiometer, or rheostat used in a regenerative receiver to control the amount of feedback and thereby keep regeneration within useful limits.

regenerative amplification—Amplification in which increased gain and selectivity are given by a feedback arrangement similar to that in a regenerative detector. However, the operation is always kept just below the point of oscillation.

regenerative braking—1. Dynamic braking in which the momentum, as the equipment is being braked, causes the traction motors to act as generators. A retarding force is then exerted by the return energy to the power-supply system. 2. A method of braking of an electric vehicle in which the vehicle's kinetic energy is converted to electric current that, in turn, is used to recharge the battery rather than being lost as heat.

regenerative detector—A detector circuit in which regeneration is produced by positive feedback from the output to the input circuit. In this way the amplification and sensitivity of the circuit are greatly increased.

regenerative divider—Also called a regenerative modulator. A frequency divider in which the output wave is produced by modulation, amplification, and selective feedback.

regenerative feedback—See regeneration, 1.

regenerative modulator—See regenerative divider.

Regenerative detector.

regenerative receiver—A receiver in which controlled regeneration is used to increase the amplification provided by the detector stage.

regenerative repeater—1. A repeater that regenerates pulses to restore the original shape. Used in teletypewriter and other code circuits; each code element is replaced by a new code element with specified timing, waveform, and magnitude. 2. Normally, a repeater utilized in telegraph applications. Its function is to retiming and retransmit the received signal impulses restored to their original strength. These repeaters are speed and code sensitive and are intended for use with standard telegraph speeds and codes. 3. A circuit that samples incoming signal pulses and retransmits them with perfect timing and no distortion.

Regional Bell Operating Company (RBOC)—Also called Bell Operating Companies (BOC). Local telephone operating companies that were split off from AT&T and which provide most local and intrastate telephone service in the United States.

regional channel—A standard broadcast channel within which several stations may operate at 5 kilowatts or less. However, interference may limit the primary service area of such stations to a given field-intensity contour.

regional interconnections—See interconnection, 1.

region of limited proportionality—The range of applied voltage, below the Geiger-Mueller threshold, where the gas amplification depends on the charge liberated by the initial ionizing event.

register—1. A short-term, fast-access circuit used to store bits or words in a CPU; its capacity usually is one computer word. Variations may include provisions for shifting, calculating, etc. Registers play a key role in CPU operations. In most applications the efficiency of programs is related to the number of registers. See also static shift register; dynamic shift register. 2. The relative position of all or part of the conductive pattern with respect to a mechanical feature of the board or to another pattern on the obverse side of the printed-circuit board (e.g., pattern-to-hole register or pattern-front-to-pattern-back register). 3. Also called registration. The accurate matching of two or more patterns such as the three images in color television. 4. A range of notes used for playing a particular piece or part of it (e.g., melody or harmony), particularly the range covered by a clavier or manual. 5. In an automatic-switching telephone system, the part of the system that receives and stores the dialing pulses that control the additional operations necessary to establish a telephone connection. 6. A device that can store information, usually that contained in a small subset or word of the total within a digital computer system. 7. Logic elements (gates, flip-flops, shift registers) that, taken together, store 4-, 8-, or 16-bit numbers. They are

essentially for temporary storage, in that the contents usually change from one instruction cycle to the next. In fact, much of a microprocessor's operation can be learned by studying the registers, which take part in nearly all operations. 8. An electromechanical device that marks a paper tape in response to signal impulses received from transmitting circuits. A register may be driven by a prewound spring mechanism, an electric motor, or a combination of these. 9. One word of memory. Usually implemented in fast flip-flops, directly accessible to a processor. Most MPUs include a set of internal registers, which can be accessed much faster than the main memory. 10. A special section of primary storage in a computer where data is held while it is being worked on.

register control—Any device that provides automatic register. In photoelectric register control, a light source and phototube from a scanning head. Whenever a special mark or a part of the design printed on a continuous web of paper arrives at the scanning head, the amount of light reaching the phototube changes. If necessary, the web is then moved slightly to bring it back into register.

register file—1. A small area of memory in which several data elements, or registers, can be accessed simultaneously, rather than one by one. 2. A bank of multiple-bit registers that can be used as temporary storage locations for data or instructions (sometimes referred to as a stack).

register length—The number of digits, characters, or bits that a computer register can store.

register mark—In printed circuits, a mark used to establish the relative position of one or more printed-wiring patterns or portions of patterns with respect to their desired locations on the base.

register of a meter—In a meter, the part that registers the revolutions of the rotor, or the number of impulses received from or transmitted to the meter, and gives the answer in units of electric energy or other quantity measured.

registration—1. The accuracy of relative position or concentricity of all functional patterns on any mask with the corresponding patterns of any other mask of a given device series of masks when the masks are properly superimposed. 2. The degree of proper alignment of a circuit pattern on the substrate. 3. The degree of accuracy of pattern position with respect to patterns on other layers of double-sided or multilayer boards.

registration marks—The marks used for aligning successive processing masks.

registration of a meter—The apparent amount of electric energy (or other quantity being measured) that has passed through the meter, as shown by the register reading. It is equal to the register reading times the register constant. During a given period, it is equal to the register constant times the difference between the register readings at the beginning and end of the period.

registry—The superposition of one image onto another (e.g., in the formation of an interlaced scanning raster).

regular—Pertaining to reflection, refraction, or transmission in a definite direction rather than in a diffused or scattered manner.

regulated power supply—A unit that maintains a constant output voltage of current for changes in line voltage, output load, ambient temperature, or time.

regulating device—A device that functions to regulate a quantity or quantities such as voltage, current, power, speed, frequency, temperature, and load, at a certain value or between certain limits for machines, tie lines, or other apparatus.

regulating transformer—A transformer for adjusting the voltage or the phase relation (or both) in steps,

usually without interrupting the load. It comprises one or more windings excited from the system circuit or a separate source, and one or more windings connected in series with the system circuit.

regulating winding—A supplementary transformer winding connected in series with one of the main windings and used for changing the ratio of transformation or the phase relationship, or both, between circuits.

regulation—1. The difference between the maximum and minimum voltage drops within a specified anode-current range in a gas tube. 2. The holding constant of some condition (e.g., voltage, current, power, or position). 3. In a power supply, the ability to maintain a constant load voltage or load despite changes in line voltage or load impedance. 4. The change in value of dc output voltage of a power supply resulting from a change in ac input voltage over the specified range from low (105 V ac) to high (125 V ac) or from high line to low line. Normally specified as the plus or minus change around the nominal ac input voltage.

regulation of a constant-current transformer—The maximum departure of the secondary current from its rated value, expressed in percent of the rated secondary current, with the rated primary voltage and frequency applied and at the rated secondary power factor and with the current variation taken between the limits of a short circuit and rated load.

regulation of a constant-potential transformer—The change in secondary voltage, expressed in percent of rated secondary voltage, that occurs when the rated kVA output at a specified power factor is reduced to zero, with the primary impressed terminal voltage maintained constant. In the case of a multiwinding transformer, the loads on all windings or specified power factors are to be reduced from the rated kVA to zero simultaneously.

regulator—1. A device whose function is to maintain a designated characteristic at a predetermined value or to vary it according to a predetermined plan. 2. A device used to maintain a desired output voltage or current constant regardless of normal changes to the input or to the output load.

regulator tube—A two-electrode glow-discharge gas tube that has an essentially constant voltage drop. When series-connected with a resistance across a dc source, the tube will maintain a constant dc voltage across its terminal, with wide variations in the dc source voltage.

reignition—The generation of multiple counts within a radiation-counter tube by the atoms or molecules excited or ionized in the discharge accompanying a tube count.

reignition voltage—Also called restriking voltage. That voltage that is just sufficient to reestablish conduction of a gas tube if applied during the deionization period. It varies inversely with time during the deionization period.

Reike diagram—A polar-coordinate load diagram for microwave oscillators, particularly for klystrons and magnetrons.

Reinartz crystal oscillator—A crystal-controlled vacuum-tube oscillator in which the crystal current is kept low by placing in the cathode lead a resonant circuit tuned to half the crystal frequency. The resultant regeneration at the crystal frequency improves the efficiency, but without the problem of uncontrollable oscillations at other frequencies.

reinforced insulation—An insulation providing protection against electrical shock hazard; equivalent to double insulation.

regulating winding — relative interference effect

reinsertion of a carrier—Combining a locally generated carrier signal in a receiver with an incoming suppressed-carrier signal.

reinstalling—Installing a program onto a computer for a second time in order to overwrite the old software and potentially fix a problem.

rejection band—The frequency range below the cutoff frequency of a uniconductor waveguide.

rejector—Filter or part of a circuit that rejects a particular frequency or band of frequencies.

rejector circuit—A circuit that suppresses or eliminates signals of the frequency to which it is tuned.

rejuvenator—A device or instrument for restoring the emissivity of a thermionic cathode by running it at an elevated temperature for a short period of time.

rel—A unit of reluctance, equal to one ampere-turn per magnetic line of force.

relative accuracy—1. The possible deviation among the standards in a group. 2. The input-to-output error as a fraction of full scale with gain and offset errors adjusted to zero. Relative accuracy is a function of linearity.

relative address—1. A designation used to identify the position of a memory location in a computer routine or subroutine. 2. A label used to identify a word in a routine or subroutine with respect to its position in that routine or subroutine. 3. An address of a machine instruction that is referred to an origin address. For example, consider the relative address 14, which is translated into the absolute address Origin R + 14, where R is, typically, the contents of the program counter. Relative addressing allows the generation of position-independent code.

relative addressing—A method of memory addressing in which the desired information is located by adding a distance from a pointer to the pointer. The location in relation to the base address or pointer is known.

relative bearing—The bearing in which the direction of the reference line is the heading of the vehicle.

relative binary—The primary form in which information is generated by a link editor and as such has all internal links resolved and is capable of holding address references such that they are relative, usually to one single base address.

relative coding—In a computer, coding in which all addresses refer to an arbitrarily selected position, or in which all addresses are represented symbolically.

relative damping of an instrument—Also called specific damping. Ratio of the actual damping torque at a given angular velocity of a moving element to the damping torque that would produce critical damping at this same angular velocity.

relative detector response—A plot showing how the response (ability to detect a signal) varies with wavelength.

relative dielectric constant—Ratio of the dielectric constant of a material to that of a vacuum. The latter is arbitrarily given a value of 1.

relative gain of an antenna—The gain of an antenna in a given direction when the reference antenna is a half-wave loss-free dipole isolated in space whose equatorial plane contains the given direction.

relative humidity—1. Ratio of the quantity of water vapor in the atmosphere to the quantity that would saturate at the existing temperature. Usually expressed as a percentage. 2. Ratio of the pressure of water vapor to that of saturated water vapor at the same temperature.

relative interference effect—With respect to a single-frequency electric wave in an electroacoustic system, the ratio (usually expressed in decibels) of the

amplitude of a wave of specified reference frequency to that of the given wave when the two waves produce equal interference effects.

relative luminosity—Ratio of the actual luminosity at a particular wavelength to the maximum luminosity at the same wavelength.

relative Peltier coefficient—The Peltier coefficient of a couple made up of the given material as the first-named conductor and a specified standard conductor, commonly platinum, lead, or copper.

relative permeability—1. Ratio of the magnetic permeability of one material to that of another, or of the same material under different conditions. 2. The permeability of a body relative to that of a vacuum.

relative plateau slope—The average percentage change in the counting rate of a radiation-counter tube near the midpoint of the plateau, per increment of applied voltage. It is usually expressed as the percentage change in counting rate per 100-volt change in applied voltage.

relative power—A power level referred to another power level.

relative power gain—Of one transmitting or receiving antenna over another, the measured ratio of the signal power one antenna produces at the receiver input terminals to the signal power produced by the other, the transmitting power level remaining fixed.

relative refractive index—Ratio of the refractive indices of two media.

relative response—The ratio, usually expressed in decibels, of the response under some particular conditions to the response under reference conditions (which should be stated explicitly).

relative Seebeck coefficient—The Seebeck coefficient of a couple made up of the given material as the first-named conductor and a specified standard conductor such as platinum, lead, or copper.

relative spectral response—The output or response of a device as a function of wavelength normalized to the maximum value.

relaxation—An action requiring an observable length of time for initiation in response to a sudden change in conditions.

relaxation circuit—A circuit arrangement, usually of vacuum tubes, reactances, and resistances, that has two states or conditions, one, both, or neither of which may be stable. The transient voltage produced by passing from one to the other, or the voltage in the state of rest, can be used in other circuits.

relaxation inverter—An inverter that uses a relaxation-oscillator circuit to convert dc power to ac power.

relaxation oscillator—1. An oscillator that generates a nonsinusoidal wave by gradually charging and quickly discharging a capacitor or an inductor through a resistor. The frequency of a relaxation oscillator may be self-determined or determined by a synchronizing voltage derived from an external source. 2. An oscillator characterized by two semistable states such that when changed to either state the system will, after a time, recover the other state without external excitation. 3. An oscillator whose frequency is determined by the time required to charge a capacitor through a resistor. It produces a sawtooth output.

relaxation time—1. The time an exponentially decaying quantity takes to decrease in amplitude by a factor of 0.3679. 2. The average time between collisions of an electron with the lattice.

relay—1. An electromechanical device in which contacts are opened and/or closed by variations in the conditions of one electric circuit and thereby effect the

operation of other devices in the same or other electric circuits. 2. A transmission forwarded by way of an intermediate action. 3. An intermediate station on a multilink radio system. 4. An electromechanical device that opens or closes electrical contacts when energized by an isolated electrical coil circuit. Basically an electromagnetic solenoid arranged to open or close a spring-loaded armature. The construction and insulation of this device permits it to switch high-current or high-voltage power when an electromagnet is actuated by a low-power coil. Relays are also used for the remote switching of low signal levels in communications and telecommunications and may have many different contact combinations. 5. A device used to connect (make) or interrupt (break) an electrical current path. Unlike a switch, which is usually actuated by hand or by external mechanical action, a relay has its own built-in actuating mechanism that is responsive to a controlling voltage or current.

Relay, I.

relay bias—Bias produced by a spring on an electromagnet. By acting on the relay armature, the spring tends to hold it in a given position.

relay broadcast station—A station licensed to retransmit, from points where wire facilities are not available, the programs from one or more broadcast stations.

relay center—A central point at which switching of messages takes place.

relay contacts—Contacts that are closed or opened by the movement of a relay armature.

relay driver—A circuit with the high-voltage and high-current switching capability necessary for actuation of electromechanical relays.

relay drop—A relay activated by an incoming ringing current to call an operator's attention to a telephone subscriber's line.

relay flutter—Erratic rather than positive operation and release of a relay.

relay function—Control of power in one circuit by means of a low-power, isolated signal in another circuit. See figure on page 639.

relay magnet—A coil and iron core forming an electromagnet that, when energized, attracts the armature of a relay and thereby opens or closes the relay contacts.

relay receiver—A specific assembly of apparatus that accepts a sound or television relay signal at its input terminals and delivers the amplified signal at its output terminals.

relay selector—A relay circuit associated with a selector, consisting of a magnetic impulse counter, for registering digits and holding a circuit.

Relay function.

relay station— See relay transmitter.

relay-station satellite— An artificial earth satellite intended to receive radio signals from the earth and retransmit them on command to other receiving stations.

relay system— Dial switching equipment made up principally of relays instead of mechanical switches.

relay transmitter— Also called a repeater or relay station (but only if the signal is reduced to a composite picture signal at a standard impedance level and polarity between the receiver and transmitter). The specific assembly of apparatus that accepts a sound or television relay input signal from the relay receiver and rebroadcasts it to another station outside the range of the operating station.

release— 1. An electromagnetic device that opens a circuit breaker automatically or allows a motor starter to return to its off position when tripped by hand, by an interruption of power-supply operation, or by an excessive current. 2. The condition attained by a relay when it has been deenergized, all contacts have functioned, and the armature (if applicable) has attained a fully opened position. 3. See disconnect, 3. 4. A system service that informs the operating system that a task no longer requires use of a resource.

release current— 1. The maximum current needed to fully release a relay after it has been fully closed. 2. That value of current at which a relay will just release after having been operated for an appreciable time.

release force— The value to which the force on the actuator of a momentary-contact switch must be reduced to allow the contacts to snap from the operated contact position to the normal contact position.

release time— 1. The time interval from coil deenergization of a reed relay to the functioning time of the last contact to function. Where not otherwise stated, the functioning time of the contact in question is taken as its initial functioning time (that is, it does not include contact bounce time). 2. Also called hold time. The time interval during which data must not change after a flip-flop has been clocked. 3. The time for a gain-changing device (such as a compressor/limiter or an expander) to recover from changes in signal level.

releasing position— That position of the actuator of a momentary-contact switch at which the contacts snap from the operated contact position to the normal contact position.

reliability— 1. The probability that a device will perform adequately for the length of time intended and under the operating environment encountered. 2. The characteristic of an item expressed by the probability that it will perform a required function under stated conditions for a stated period. 3. The probability of failure-free performance of a device system or component for a given period under certain stress conditions. Probability of success. 4. A measure of a good device's ability to meet the required specifications for a given period. 5. The ability of an item to perform a required function under stated conditions for a specified period of time.

reliability assurance— The management and technical integration of the reliability activities essential in maintaining reliability achievements, including design, production, and product assurance.

reliability control— The scientific coordination and direction of technical reliability activities from a system viewpoint.

reliability data— 1. Data related to the frequency of failure of an item, equipment, or system. This data may be expressed in terms of failure rate, mean time between failures (MTBF), or probability of success. 2. Data contained in comprehensive documents that provide a detailed history of the reliability evaluation of component parts, component assemblies, etc., or the entire program during the design, development, production, and major product improvement phases of an equipment, weapon, or weapon system in which engineering studies have been performed to select the most reliable product for the intended application.

reliability engineering— 1. The establishment, during design, of an inherently high reliability in a product. 2. The science of including those factors in the basic design that will ensure the required degree of reliability.

reliability index— A quantitative measure of the reliability of equipment or systems.

reliability test— Test and analyses carried out in addition to other type tests and designed to evaluate the level of reliability in a product, etc., as well as the dependability, or stability, of this level relative to time and use under various environmental conditions.

reliable control— Equipment that performs control functions similar to those performed by conventional relay panels and electromechanical devices. Commands are stored in the PC's built-in program. Control actions (outputs) are initiated by signals from sensing devices (inputs) located in the machine or process being controlled. Input can be supplied by limit switches, photoelectric cells, timers, temperature and pressure sensors, or similar devices.

relieving anode— In a pool-cathode tube, an auxiliary anode that provides an alternative conducting path to reduce the current to another electrode.

relocatability— That characteristic of a compiled or assembled computer program segment that makes possible loading (locating) it into any region of memory.

relocatable— 1. Computer program or routine that does not contain fixed addresses, and can therefore be easily relocated elsewhere in the memory. 2. Object programs that can reside in any part of system memory. The actual starting address is established at load time by adding a relocation offset to the starting address. Relocatable code is typically composed of position-independent code.

relocatable assembler— A program that translates object code from an assembly-language source program, using memory locations specified as displacements from a relative origin or as external references. This facilitates the running of programs in any memory area.

relocatable binary— The form in which information is generated by a compiler or assembler and which is the primary input to a link editor.

relocatable macro assembler— A program that permits instruction groups to be combined for execution, using symbolic addresses.

relocatable program— A software program so written that it can be moved to and executed from many different areas of memory.

relocate— In computer programming, to move a routine from one part of storage to another and adjust the necessary address references to permit execution of the routine in its new location.

relocation dictionary—In a computer, the part of an object or load module that provides identification of all relocatable address constants in the module.

reluctance—1. The resistance of a magnetic path to the flow of magnetic lines of force through it. It is the reciprocal of permeance and is equal to the magnetomotive force divided by the magnetic flux. 2. Property of a magnetic circuit that determines the total magnetic flux in the circuit when a given magnetomotive force is applied.

reluctance pickup—A pickup that depends for its operation on variations in the reluctance of a magnetic circuit due to the movements of an iron stylus assembly that is a part of the magnetic circuit. The reluctance variations alternately increase and decrease the flux through two series-connected coils, inducing in them the desired ac output voltage.

reluctance-type synchronous motor—An ac motor that runs at synchronous speed without excitation because of the salient pole rotor punchings of the laminations. The rotor has a squirrel cage type winding. Made in single- and three-phase types.

reluctive transduction—The conversion of the measurand into a change in ac voltage by changing the reluctance path between two or more coils when ac excitation is applied.

reluctivity—The ability of a magnetic material to conduct magnetic flux. It is the reciprocal of permeability.

rem—A measure of physiological damage to the human body caused by radiation, calculated as the absorbed dose in rads multiplied by various factors that qualify the type of radiation and the way in which it is absorbed. *See* roentgen equivalent man.

remanence—1. The extent to which a body remains magnetized after removal of a magnetizing field that has brought the body to its saturation (maximum) magnetization. A substance with remanence is called ferromagnetic. 2. The magnetic induction that remains in a magnetic circuit after the removal of an applied magnetomotive force. (If there is an air gap in the magnetic circuit, the remanence will be less than the residual induction.)

remanent magnetization—The magnetization retained by a substance after the magnetizing force has been removed.

reminder chirp—Optional feature of a pager that emits a "chirp" every two minutes when there are unread messages.

remodulator—A device for converting amplitude modulation to audio-frequency-shift modulation for transmission over voice radio-frequency channels.

remote—*See* field pickup.

remote access—1. Having to do with communication with a data-processing facility by stations at a distance from the facility. 2. Pertaining to communication with a computer processor by terminal stations that are distant from that processor.

remote alarm—An alarm signal that is transmitted to a remote monitoring station. *See also* local alarm.

remote batch—A method of entering jobs into a computer from a remote terminal in a conversational mode, for processing later in a batch processing mode. In this mode a plant or office geographically distant from the central computer can load in a batch of transactions, transmit them to the computer, and receive the results by mail or via direct transmission to a printer or other output device at the remote site.

remote control—1. Any system of control performed from a distance. The control signal may be conveyed by intervening wires, sound (ultrasonics), light, or radio. 2. Manual control, with the control operator monitoring the operation on duty at a control point located elsewhere than at the station transmitter, such that the

associated operating adjustments are accessible through a control link. 3. A method whereby a device is programmable via its electrical interface connection in order to enable the device to perform different tasks.

remote-cutoff tube—Also called a variable- μ or extended-cutoff tube. An electron tube used mainly in rf amplifiers. The control-grid wires are farther apart at the center than at the ends. Therefore, the amplification of the tube does not vary in direct proportion to the bias. Also, some plate current will flow regardless of the negative bias on the grid.

remote error sensing—A means by which the regulator circuit of a related power supply senses the voltage directly at the load. This connection is used to compensate for a voltage drop in the connecting wires.

remote indicator—1. A radar indicator that is connected in parallel with a primary indicator. 2. An indicator located some distance away from the data-gathering element.

remote job entry—The process of entering data-processing jobs or tasks for execution from an input device, such as a terminal that is remote from the processing computer and connected to the computer by a communication line.

remote line—A program transmission line between a remote-pickup point and the studio or transmitter site.

remote/local—Refers to device connection to a given computer with remote devices attached directly over communications lines and local devices attached directly to a computer channel; in a network environment the computer itself may be a remote device to the CPU controlling the network.

remotely adjustable timer—A time delay having external leads to which a variable or fixed resistor can be attached.

remote metering—*See* telemetering.

remote pickup—Transmitting a program that originates away from the studio to the studio or transmitter over telephone lines or a radio link.

remote plan-position indicator—*See* PPI repeater.

remote programming—A power supply feature whereby the controlled output parameter, voltage, or current may be controlled through the application of external resistance, voltage signals, or current signals to designated external terminals.

remote sensing—1. In a power supply, terminations that allow the regulator to sense and regulate the output voltage at a remote location, usually the load. This connection is used to compensate for voltage drops in the power leads. The maximum voltage drop in both power leads must be specified. 2. Technique that utilizes electromagnetic energy to detect and quantify information about an object that is not in contact with the sensing apparatus.

remote station—Data terminal equipment for communication with a data-processing system that is distant electrically or in terms of time or space.

remote-station alarm system—An alarm system that employs remote alarm stations, usually located in building hallways or on city streets.

remote subscriber—A network subscriber without direct access to the switching center, but with access to the circuit through a facility such as a base message center.

remote terminal—1. A terminal that is a substantial distance from the central computer. Usually it accesses the computer through a telephone line or other type of communication link. 2. An input-output control unit and one or more input/output devices at some distance from the central processing unit.

removable contact—A contact that can be mechanically joined to or removed from an insert.

Usually, special tools are required to lock the contact in place or remove it for repair or replacement.

render—A computer graphics process that removes hidden surfaces and jagged edges from computer-generated 3D models by adding shades, texture, depth, and other realistic attributes.

renewable fuse—A fuse that may be readily restored to operation by replacing the fused link.

reoperate time—The release time of a thermal relay.

rep—Abbreviation for roentgen equivalent physical.

repaint—To redraw a display image on a CRT to reflect its updated status.

repair—To restore a failed module or system to a specified operable condition.

repairing—The act of restoring the functional capability of a defective part without necessarily restoring appearance, interchangeability, and uniformity.

repeatability—1. The ability of a device or instrument to come back to the same reading after a certain length of time. 2. The ability of an instrument to repeat its readings taken when deflecting the pointer up-scale, compared to the readings taken when deflecting the pointer down-scale, expressed as a percentage of the full-scale deflection. 3. See precision, 2. 4. The ability of a transducer to reproduce output readings when the same measurand value is applied to it consecutively, in the same direction. (Short time duration.) 5. The precision with which a sensor will give the same output or value among repeated temperature measurements.

repeatability error—The inability to reproduce the same output readings when a given level of measurand is applied repeatedly in the same direction.

repeat-cycle timer—A timer that has any number of load contacts and that continues to repeat its time program as long as power is applied.

repeater—1. An FM, TV, facsimile, or similar station that receives a signal on some input frequency and automatically transmits the received signal on some output frequency. The purpose of a repeater is to extend the communication range between a group of stations. The repeater generally consists of a receiver with its antenna, a control unit, and a transmitter with its antenna. 2. Switch by which originating central-office, calling-telephone dialed pulses are repeated to switches at a distant office. 3. Relay circuit in dial signaling, which amplifies and repeats dial pulses received from one circuit into another. 4. A device used to amplify and/or reshape signals. 5. A sensitive receiver coupled to a high-power transmitter located on top of a tall building or high hill. 6. A device that serves to amplify signals that have become too weak. 7. A device that converts a received optical signal to its electrical equivalent, reconstructs the source signal format, amplifies it, and reconverts it to an optical output signal. 8. A device that serves as an interface between two circuits, receiving signals from one circuit and transmitting them to the other circuit.

repeater control operator—A licensed amateur designated by a repeater trustee who offers assistance with autopatch and listens for inappropriate use of the repeater. (This is different from the FCC's definition of a control operator, which is anyone in control of an amateur transmitter.)

repeater facility—Radio equipment needed to relay radio signals between central stations, satellite stations, and/or protected premises.

repeater jammer—Equipment intended to confuse or deceive the enemy by causing its equipment to present false information regarding azimuth, range, number of targets, etc. This result is achieved by a system that

intercepts and reradiates a signal on the frequency of the enemy equipment.

repeater station—1. Station licensed to automatically retransmit the radio signals of other (amateur) radio stations. 2. See relay transmitter.

repeating coil—1. An audio-frequency transformer, usually with a 1:1 ratio, for connecting two sections of telephone line inductively to permit the formation of simplex and phantom circuits. 2. Telephone industry term for a voice-frequency transformer.

repeating-coil bridge cord—A way of connecting the common office battery to the midpoints of a repeating coil, which is bridged across the cord circuit.

repeating flash tube—A flash tube that, by producing rapid, brilliant flashes, permits night aerial photographs to be taken from as high as two miles.

repeating timer—A timer that repeats each operating cycle automatically until excitation is removed.

repeller—Sometimes called a reflector. 1. An electrode whose primary function is to reverse the direction of an electron stream. 2. The element in a reflex klystron tube that reflects the electrons back toward the grid.

reperforator—1. A device that converts teletype-writer signals into perforations on tape instead of the usual typed copy on a roll of paper or ticker tape. 2. A machine that reads one punched paper tape or card and punches the same information into another paper tape or card.

reperforator/transmitter—An integrated unit for temporarily storing traffic for retransmission. It consists of a paper-tape punch and a paper-tape reader.

repertory dialer—A device that automatically places a telephone call to any one of the phone numbers stored therein.

repertory dialing—The process of dialing a complete telephone number, or area code plus number, by pressing a single button key. The telephone set (or accessory dialer) has a number of buttons that can be programmed to produce an individual telephone number.

repertory instruction—1. A set of instructions that a computing or data-processing system can perform. 2. A set of instructions assembled by an automatic coding system.

repetition equivalent—A measure of the quality of transmission experienced by the subscribers using a complete telephone connection. It represents a combination of the effects of volume, distortion, noise, and all other subscriber reactions and usage.

repetition frequency—The number of repetitions of an event per unit time.

repetition instruction—A computer instruction that calls for one or more instructions to be executed an indicated number of times.

repetition rate—1. The number of repetitions of an event per unit time. For example, in radar, the rate (usually expressed in pulses per second) at which pulses are transmitted (also called pulse repetition frequency, recurrence rate, or repetition frequency). 2. The number of repetitions per unit time requested by users of a telephone connection.

repetitive logic—A large-scale repetition of logic functions (or cell structures), such as in a memory or shift register. A semiconductor memory, for example, is simply a repetition of identical structures of transistors and their interconnects. As a result, repetitive-logic circuits on a chip generally have a checkerboard pattern and, thus, are relatively easy to fabricate.

repetitively pulsed laser—A pulsed laser that emits a recurring pulsed output. Frequency of the pulses emitted is known as pulsed recurrence frequency, PRF. When the PRF or duty cycle is very high, repetitively

pulsed lasers illustrate properties like those of the cw laser.

repetitive peak inverse voltage—The maximum allowable instantaneous value of reverse (negative) voltage that may be repeatedly applied to the anode of an SCR with the gate open. This value of peak inverse voltage does not represent a breakdown voltage, but it should never be exceeded (except by the transient rating if the device has such a rating).

repetitive peak off-state voltage—The highest instantaneous value of the off-state voltage that occurs across a thyristor, including all repetitive transient voltages but excluding all nonrepetitive transient voltages.

repetitive peak on-state current—The peak value of the on-state current, including all repetitive transient currents.

repetitive unit—A type of circuit that appears more than once in a computer.

replacement theory—The mathematics of deterioration and failure, used in estimating replacement costs and selecting optimum replacement policies.

reply—In transponder operation, the radio-frequency signal or signals transmitted as a result of an interrogation.

repolarization—The process by which the normal resting potential of a biological cell is restored after the cell has fired, or depolarized.

report—1. The output document produced by a data-processing system. 2. An application data display or print-out containing information in a user-designed format. Reports include operator messages, part records, production lists, etc. Initially entered as messages, reports are stored in a memory area separate from the user's program.

report generation—1. In a computer, production of complete output reports from only a specification of the desired content and arrangement and from specifications regarding the input file. 2. The printing or displaying of user-formatted application data by means of a data terminal. Report generation can be initiated by means of either the user's program or a data terminal keyboard. *See* message; report.

report generator—A special computer routine designed to prepare an object routine that, when later run on the computer, produces the desired report.

representative calculating time—A measure of the performance speed of a computer; it is the time required for performance of a specified operation or series of operations.

reproduce—In a computer, to prepare a duplicate of stored information.

reproduce head—An electromagnetic transducer that converts the remanent flux pattern in a magnetic tape into electric signals during the reproduce (playback) process.

reproducer—A device used to translate electrical signals into sound waves.

reproducibility—1. The exactness with which measurement of a given value can be duplicated. 2. *See* precision, 2.

reproducing stylus—A mechanical element that hollows the modulations of a record groove and transmits the mechanical motion thus derived to the pickup mechanism.

reproduction speed—In facsimile, the area of copy recorded per time.

reprogrammable ROM—A ROM that can be programmed any number of times. Generally, however, the information stored in a reprogrammable ROM is changed very seldom.

repulsion—The mechanical force that tends to push apart adjacent conductors that carry currents in opposite

directions, or tends to separate bodies having like electrostatic charges or magnetic poles of like polarity.

repulsion-induction motor—A constant- or variable-speed repulsion motor with a squirrel-cage winding in the rotor in addition to the regular winding.

repulsion motor—A single-phase motor in which the stator winding is connected to the source of power, and the rotor winding to the commutator. Brushes on the commutator are short-circuited and are placed so that the magnetic axis of the brush winding is inclined to that of the stator winding. This type of motor has a varying speed characteristic.

repulsion-start, induction-run motor—A single-phase motor that has the same windings as a repulsion motor but operates at a constant speed. The rotor winding is short-circuited (or otherwise connected) to give the equivalent of a squirrel-cage winding. It starts as a repulsion motor, but operates as an induction motor with constant-speed characteristics.

request repeat system—A system that uses an error-detecting code and is arranged so that when a signal is detected as being in error, a request for retransmission of the signal is initiated automatically.

request-response time—The interval between an operator's request for a display and the moment it appears on the screen.

required voltage (engine or vehicle)—The voltage required to fire the spark plugs. Requirement data is obtained using the same instrumentation as for available voltage runs, but with all spark plug leads connected. Values plotted are the maximum voltage observed, viewing all cylinders simultaneously. Requirements are usually determined with the engine operating at full load (wide-open throttle) and under a variety of part-load conditions to ascertain the maximum required voltages.

reradiation—1. Scattering of incident radiation. 2. Radiation from a radio receiver resulting from insufficient isolation between the antenna circuit and the local oscillator and causing undesirable interference in other receivers.

recording—The process of making a recording by reproducing a recorded sound source and recording this reproduction. *See also* dubbing.

recording system—An association of reproducers, mixers, amplifiers, and recorders capable of being used for combining or modifying various sound recordings to provide a final sound record. Recording of speech, music, and sound effects may be so combined.

rerun—Also called rollback. 1. To run a computer program (or a portion of it) over again. 2. To repeat an entire transmission. 3. In a computer, a system that will restart the running program after a system failure. Snapshots of data and programs are stored at periodic intervals and the system rolls back to restart at the last recorded snapshot.

rerun point—In a computer program, one of a set of preselected points located in a computer program such that if an error is detected between two such points, the problem may be rerun by returning to the last such point instead of returning to the start of the problem.

rerun routine—A computer routine designed to be used, in the event of a malfunction or mistake, to reconstitute a routine from the previous rerun point.

reset—1. To restore a storage device to a prescribed state. 2. To place a binary cell in the initial, or 0, state. *See also* clear. 3. An input to a binary counter or register that causes all binary elements to assume the 0 logical state or the minimum binary state. 4. The technique of returning an electronic device to its starting point. Some equipment offers automatic reset; other apparatus offer manual or automatic and manual reset. 5. To restore a

device to its original (normal) condition after an alarm or trouble signal.

reset action—A type of control in which correction is proportional to both the length of time and the amount that a controlled process has deviated from the desired value, and provision is made to ensure that the process is returned to its set point.

reset button—A button that restarts a computer without turning power off and on.

reset pulse—A drive pulse that tends to reset a magnetic cell.

reset rate—The number of corrections made per unit of time by a control system; it usually is expressed in terms of the number of repeats per minute.

reset terminal—Also called clear terminal or zero-input terminal. In a flip-flop, the input terminal used to trigger the circuit from its second state back to its original state.

reset time—1. A timer that can be reset by electrical means. May be either an on-delay or off-delay type. 2. A timer with one or more circuits that spring-reset to zero when the clutch is disengaged. 3. The period required from the time of the reset command until a timer is fully returned to the before-start conditions ready for the next cycle.

resident assembler—An assembler that runs on the machine for which it generates code. Eliminates the need for another computer system or time-sharing service, as required by a cross assembler.

residual—1. The difference between any value and some estimate of the mean of such values; e.g., residuals from a curve of regression. (Residual unbalance.) 2. The complement of a set is called a residual set. 3. Pertaining to a measure of the output of a transducer under static conditions and with no stimulus applied.

residual charge—1. The charge remaining on the plates after an initial discharge of a capacitor. 2. The small charge that remains in the dielectric of a capacitor after a quick discharge.

residual current—1. The vector sum of the currents in the several wires of an electric supply circuit. 2. Current through a thermionic diode in the absence of anode voltage; it results from the velocity of the electrons emitted by the heated cathode.

residual deviation—Apparent modulation due to noise and/or distortion in the transmitter.

residual discharge—A discharge of the residual charge of a capacitor remaining after the initial discharge.

residual error—The direction-finding errors remaining after errors due to site and antenna effects have been minimized.

residual field—The magnetic field left in an iron field structure after excitation has been removed.

residual flux—1. The value of magnetic induction that remains in a magnetic circuit when the magnetomotive force is reduced to zero. 2. In a uniformly magnetized sample of magnetic material, the product of the residual flux density and the cross-sectional area. Residual flux is indicative of the output that can be expected from a tape at long wavelengths.

residual flux density—The magnetic flux density that exists at zero magnetizing field strength when a sample of magnetic material has undergone symmetrically cyclical magnetization.

residual FM—*See* incidental FM.

residual gases—The small amounts of gases remaining in a vacuum tube despite the best possible exhaustion by vacuum pumps.

residual induction—1. The magnetic induction that remains in a magnetized material when the effective magnetizing force has been reduced to zero. When the

material is in a symmetrically cyclic magnetic condition, the residual induction is termed the "normal residual induction." Letter symbol: B_r . 2. The magnetic induction corresponding to zero magnetizing force in a magnetic material that is in a symmetrically cyclically magnetized condition. Note: The European definitions of residual induction and remanence are interchanged. Thus, the meaning of these two words can vary, depending on the author.

residual ionization—Ionization of air or other gas not accounted for in a closed chamber by recognizable neighboring agencies.

residual losses—In a magnetic core, the difference between the total losses and the sum of the eddy-current and hysteresis losses.

residual magnetic induction—Magnetic induction remaining in a ferromagnetic object after the magnetizing force has been removed. The amount depends on the material, shape, and previous magnetic history.

residual magnetism—The magnetism that remains in the core of an electromagnet after the operating circuit has been opened.

residual modulation—*See* carrier noise level.

residual screw—A brass screw in the center of a relay armature. It is used to adjust the residual air gap between the armature and the coil core to prevent residual magnetism from holding the armature operated after the relay operating circuit has opened.

residual torque—Nonenergized detent torque arising from permanent-magnet effects and bearing friction of a stepper motor.

residual voltage—1. The vector sum of the voltages to ground of the several phase wires in an electric supply circuit. 2. The voltage caused by dielectric absorption that appears in the capacitor terminations after the capacitor is discharged and then left with the terminations disconnected.

resin—1. One of a class of solid or semisolid, natural or synthetic organic products, generally with a high molecular weight and no definite melting point. Most resins are polymers. 2. An inorganic substance of natural or synthetic origin that is polymeric in structure and predominantly amorphous.

resist—1. A material placed on the surface of a copper-clad base material to prevent the removal by etching of the conductive layer from the area covered. 2. A material deposited on conductive areas to prevent plating of the areas covered. 3. Coating that masks areas of a board from the effects of an etchant used during manufacture.

resistance—1. A property of conductors that—depending on their dimensions, material, and temperature—determines the current produced by a given difference of potential; that property of a substance which impedes current and results in the dissipation of power in the form of heat. The practical unit of resistance is the ohm. It is defined as the resistance through which a difference of potential of 1 volt will produce a current of 1 ampere. 2. A circuit element designed to offer a predetermined resistance to current. 3. Ratio of the applied electromotive force to the resulting current in a circuit. It is a measure of the resistance of the circuit to the passage of an electric current and is measured in ohms. Its value is determined by $R = E/I$, where E is voltage in volts, and I is current in amperes.

resistance balance—The amount of resistance that is required to null the output of certain transducers or input systems.

resistance box—An assembly of resistors and the necessary switching or other means for changing the

resistance connected across its output terminals by known, fixed amounts. *See also* Wheatstone bridge.

resistance brazing — Brazing by resistance heating, the joint being part of the electrical circuit.

resistance bridge — A common form of Wheatstone bridge employing resistances in three arms. *See also* Wheatstone bridge.

resistance-bridge pressure pickup — A pressure transducer in which the electrical output is derived from the unbalance of a resistance bridge, which is varied according to the applied pressure.

resistance-bridge smoke detector — A smoke detector that responds to the particles and moisture present in smoke. These substances reduce the resistance of an electrical bridge grid and cause the detector to respond.

resistance-capacitance-coupled amplifier — An amplifier whose stages are connected by a suitable arrangement of resistors and capacitors.

resistance-capacitance coupling — Also called RC coupling. Coupling between two or more circuits, usually amplifier stages, by a combination of resistive and capacitive elements.

resistance-capacitance filter — Abbreviated RC filter. A filter made up only of resistive and capacitive elements.

resistance-capacitance oscillator — Abbreviated RC oscillator. An oscillator whose output frequency is determined by resistance and capacitance elements.

resistance coupling — Also called resistive coupling. The association of circuits with one another by means of the mutual resistance between circuits.

resistance drop — Also known as an *IR* drop. The voltage drop occurring across two points on a conductor when current flows through the resistance between those points. Multiplying the resistance in ohms by the current in amperes gives the voltage drop in volts.

resistance furnace — An electric furnace in which the heat is developed by the passage of current through a suitable resistor, which may be the charge itself or a resistor imbedded in or surrounding the charge.

resistance grounded — Grounded through a resistance, so as to limit the current that will flow in the event of a ground fault.

resistance lamp — An electric lamp used as a resistance to limit the amount of current in a circuit.

resistance loss — The power lost when current flows through a resistance. Its value in watts is equal to the resistance in ohms multiplied by the square of the current in amperes ($W = R \times I^2$).

resistance magnetometer — A magnetometer that depends for its operation on the variation in the electrical resistance of a material immersed in the field to be measured.

resistance material — A material having sufficiently high resistance per unit length or volume to permit its use in the construction of resistors.

resistance noise — *See* thermal noise, 1.

resistance pad — A network employing only resistances. It is used to provide a fixed amount of attenuation without altering the frequency response.

resistance ratio — A thermistor specification for determining resistance at a specific temperature. It is defined as the ratio of zero power resistance R_0 measured at two specified reference temperatures, usually 0°C and 25°C.

resistance soldering — A method of soldering in which a current is passed through and heats the soldering area by contact with one or more electrodes.

resistance standard — *See* standard resistor.

resistance-start motor — 1. A form of split-phase motor having a resistance connected in series with the

auxiliary winding. The auxiliary circuit opens whenever the motor attains a predetermined speed. 2. A split-phase induction motor employing a resistive auxiliary starting winding (copper alloy or iron wire) to shift the phase angle approximately 90°. Used almost exclusively for low-starting-power requirements, this winding is switched out of the circuit when the armature approaches near-synchronous speed.

resistance strain gage — A strain gage consisting of a small strip of resistance material cemented to the part under test. Its resistance changes when the strip is compressed or stretched.

resistance temperature coefficient — 1. The ratio of the resistance change of an element between two temperatures to the product of the temperature change and the original resistance. A positive value of the coefficient indicates an increase of resistance with an increase in temperature; a negative value indicates a decrease in resistance with an increase in temperature; a zero value indicates no resistance change with temperature. 2. The magnitude of change in resistance due to temperature, usually expressed in percent per degree Celsius or parts per million per degree Celsius (ppm/°C). If the changes are linear over the operating temperature range, the parameter is known as temperature coefficient.

resistance temperature detector — Also called resistance-thermometer detector. A resistor made of some material for which the electrical resistivity is a known function of the temperature. It is intended for use with a resistance thermometer and is usually in such a form that it can be placed in the region where the temperature is to be determined.

resistance temperature meter — *See* resistance thermometer.

resistance thermometer — Also called resistance temperature meter. 1. An electric thermometer that has a temperature-responsive element called a resistance temperature detector. Since the resistance is a known function of the temperature, the latter can be readily determined by measuring the electrical resistance of the resistor. 2. Thermometer using variation of resistance with temperature of some material, usually platinum, considered the standard for temperature measurement over its range.

Resistance thermometer.
